COMPUTATION BOOK

GENERAL INSTRUCTIONS

In all work in which *accuracy* and *ease of reference* are important, much depends upon carrying out the computation in a systematic manner. The following instructions, taken from the *Engineering Department Figuring Book of the Allis-Chalmers Co., serve as a guide in this matter.*

"All computations, of whatever kind, are to be made in these books, except in cases where special blanks may be provided for specific kinds of computation. Computations may be made in ink or pencil, whichever may be more convenient. Pencil figuring should be done with a soft pencil. All the work of computation should be done in these books, including all detail figuring."

"Each subject should begin on a new page, no matter how much space may be left on the previous page. The subject, with the date of beginning it, should be plainly written at the top of the first page of the subject."

"Work should be done systematically, and as neatly as consistent with rapidity. The books are, however, intended for convenience, and no unnecessary work should be done for sake of appearance only. Errors should be crossed off instead of erased, except where the latter will facilitate the work. Work should not be crowded. Paper costs less than the time which would be expended in attempting to economize space in making erasures."

"Where curves drawn on section paper (or sketches) are necessary parts of a computation, they should be pasted in the book, except where specifically otherwise provided for."

"Computations should be indexed, in the back of the book, by the person using the book."

* * * * * * * *"

Continuation of Experiment with argon lamps (stroboscopic) etc.

Yesterday Germeshausen and I tried a helium filled lamp. 1400 volts was used across it. The tube consisted of a 6" tube of 8 mm O.D. glass with 20 mm glass as ends. The cathode was a Ba Cl + Mg or al type. The light was not comparable with the light from the argon lamp. Helium pressure for this tube and voltage about 1/2 cm or less. Color bright red? hard to discribe. It may be that the helium is not pure enough. The tube was not sealed off since with helium gas since it was not bright enough. I filled it with argon at 6 cm? ± for use as a stroboscopic lamp.

Richard Evans in the spec. lab. reports that the lamp I made for him is working fine. He now gets well exposed pictures with 2 mf (400 v ?±) where he before got poorly exposed pictures with 16 mf using a Hg lamp. His argon lamps have a pressure of 4 cm and they occasionally fire by themselves. The tubes may have been hot when sealed off so that the pressure is now less than 4 cm.

The Chem dept glass blower made a tube of the variety that have been recently made by Macalaster Scientific Co and I pumped it while eating at Walters tonight. It was sealed off at 6 cm when cold after being run and flushed several times on the pump. The pressure is too high as it starts with difficulty on the circuit operated by the stroboscope.

Photographic tests.

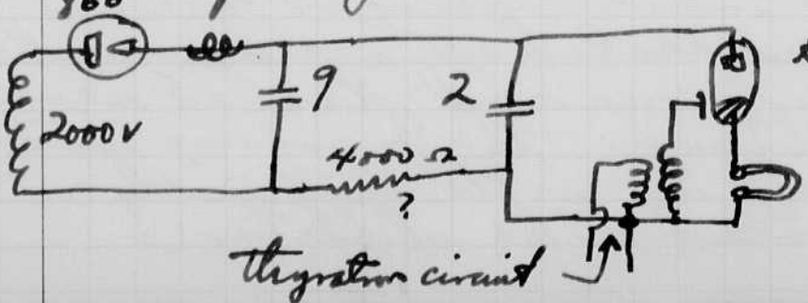
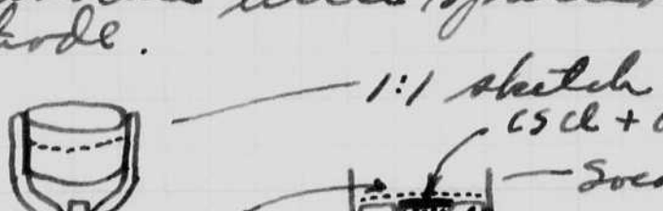
These pictures will give an indication of the amount of light from these two sources.



May 1 1936
H. E. Edgerton.

The tube shown on the opposite page does not run consistently with the spark from the stroboscope oscillator (¼" spark). The tube was opened and put on the pump again, sealed off this time at 4 cm of argon. The pressure is still slightly high although operation is satisfactory most of the time. This tube was run all day today (6 hours) and there is very little sputtering of the cathode.



Another tube identical was made this afternoon by May Bich and I pumped it during supper. I sealed it off with 2 cm of argon when cold. Works ok in circuit. Started running at 6:45 pm 2 mf 1200 ± 20 cycles.

May 4 '36 — The tube with 2 cm was put into operation for "open house" on May 2 ~~about noon~~ in the morning and it ran until about 6:30 pm at 20 cycles per second. It was used to observe water drops coming from a nozzle, the flow of water set up by a small pump. 2 micro farads at about 1200 volts were used across the tube. Some sputtering this time but it was on the anode due to arc backs, cathode spots were in evidence on the anode.

The tube broke when some water was thrown on it by one of the spectators. Then a neon tube was put in its place until 10 pm the end of the show.

May 4 '36 cont
H. E. Edgerton.

Mr. Wagringer repaired the broken tube making the length of 8 mm tubing equal to 12 inches instead of 6.

Pumped a 6" tube and filled with neon at 20 cm. 1200 volts and the strobotac oscillator were not powerful enough to kick it off.

Retubulated, baked, pumped and filled to 14 cm. This time it held over at first but ran off after warmed up.

I put 2.2 cm of argon in the 12" 8 mm diam tube.

Mr. Jones of the Saco-Lowell Shops brought in a roving machine that was cut away to show the action of a folder type of wheel. Movies were taken.

A quartz high pressure lamp was used for these pictures.

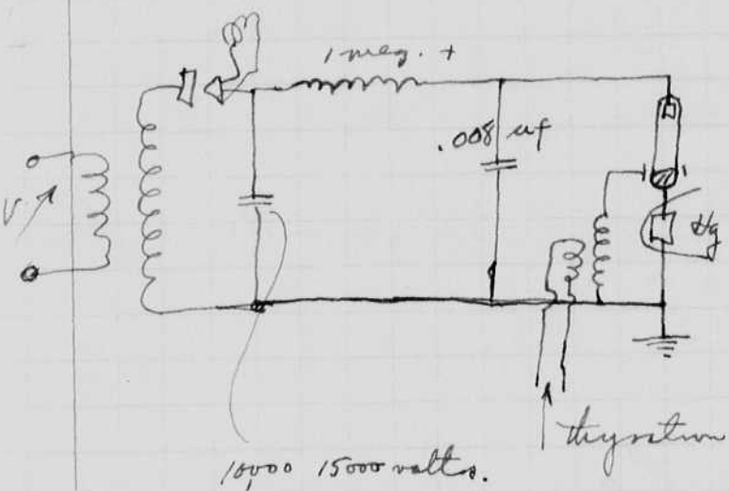
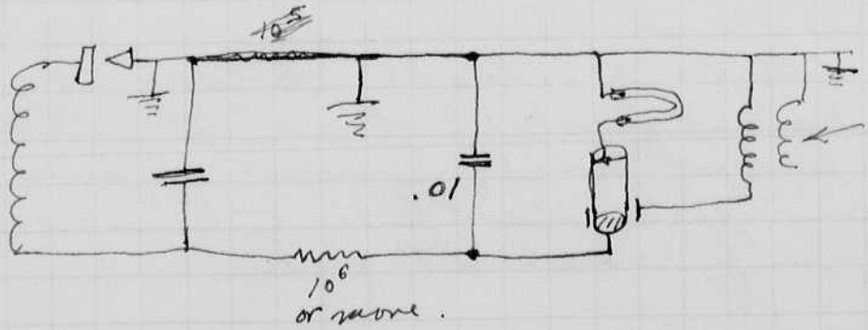
May 10 1936.

Three pyrex tubes of the type designed by Germeshausen have been made by Macalaster & Bicknell Co for use in taking pictures of bullets by reflected light. They will be filled with mercury to 1/2 atmosphere (about 350°C) and with hydrogen gas to deionize the Hg vapor. 3 cm of Hydrogen will be about the amt to try. 2 mm are now used in the 2000 volt tubes.

The circuit constants for the first tests will be the following.



The high voltage filament on the kenotron must be grounded. This was tried but sparks over heater or lamps resulted. Circuit must be changed to the following.



22 long rifle

6.3 .8a ? twin triode like 53 except with 6.3V filament.

May 22 1936.

On the 20th I spent all afternoon experimenting with a U shaped tube designed to fit the General Radio 548 stroboscope. The tube was leaky however and therefore the experiments useless.

Yesterday I made two tubes. The first was filled with 1½ cm of argon. 12 mm U tube CsCl+Al cathode. I took it over to S.R. and it worked ok in the stroboscope except for the lower capacity. Voltdrop then resulted. The second was filled with neon at 6 cm.

An interesting experiment resulted with the neon tube. If the sparker is connected to the bend of the U and there is no voltage between the electrodes, a red

glow appears in the tube which is the characteristic red glow of neon. Now if the ~~plate~~ supply voltage is connected across the ends of the tube with a 2 mf condenser (3500 ohms to about 600-900 volts) the glow in the tube is blue when the sparker is several inches from the bend of the U. If the sparker is brought closer then the condenser discharges suddenly into the tube resulting in a red flash of light which is very bright.

Germeshausens suggestion of writing Bell & Howell co. seems to be a good one. They are sending a film editor and we are going to try to adapt a stroboscope to it.

May 26 Made two argon lamps to fit portable Strobo. yesterday 2cm argon 19 cm tubing. Also made a capillary tube with 72 cm of the type that Germeshausen has been using.

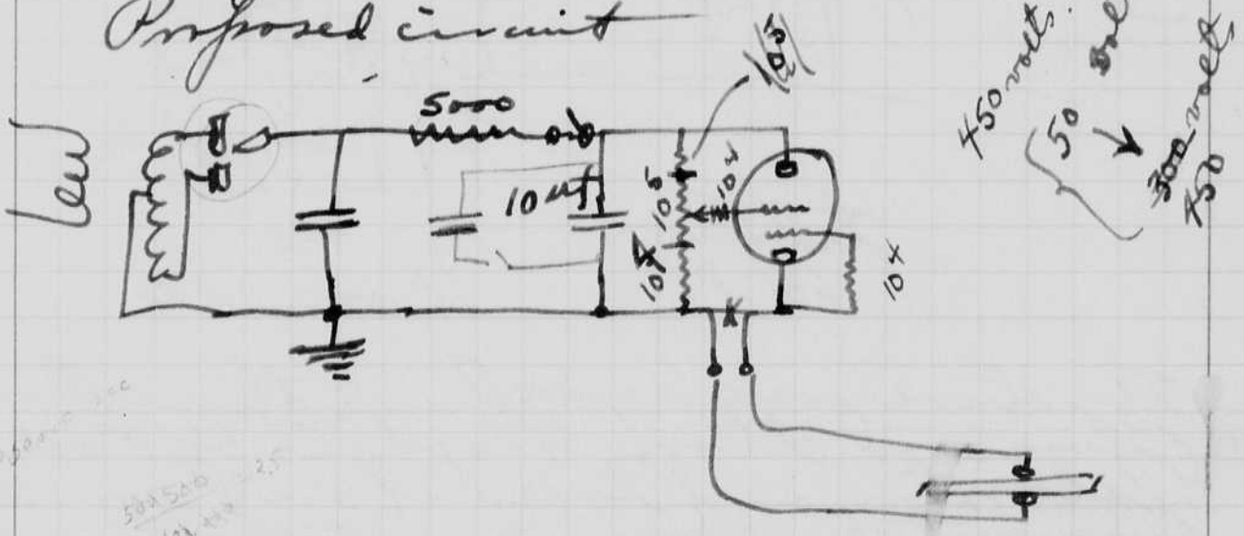
Taking more pictures of jaws with smoke for Peters (Gen'l Electric) Records in separate note book.

Discussed with Germeshausen and DeForest Eglin and Walsh the use of the stroboscopic lamp for finding cracks in ~~metals~~ steel parts. A large unidirectional current is set up to build magnetize the material. Dust is used to show up the cracks.

DeForest asked us to build him one out of it to accomplish this. I called P. Bliss, a junior, and he is coming in Monday to start.

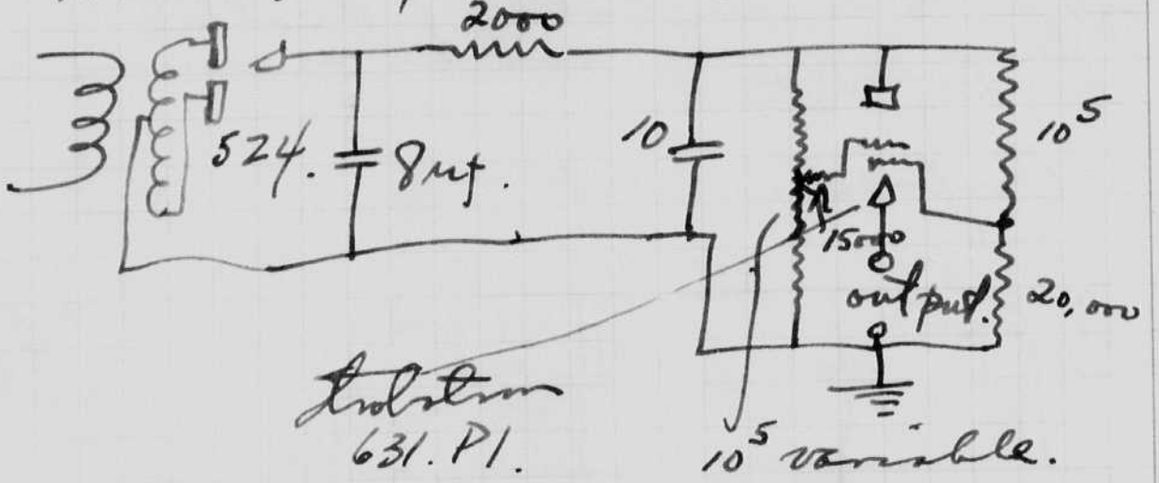
Proposed circuit



June 17 1936
Washington.

Returned last night from trip to Summit N.J. to visit my sister and to see Mr. John Long and Mr. Depke at the Bethlehem steel co. While there at the Bell Steel on Tuesday at 2:30 I showed movies and talked for about an hour to some fifty men from the laboratory and plant. Esther and two children Mary Lou and William went to Summit for the trip.

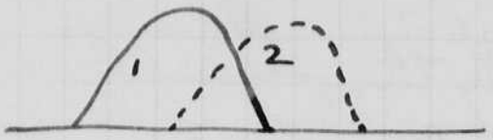
Mr. R. Bliss is wiring up a stabilizing apparatus for trial by Dr. Forest. Wiring diagram below.



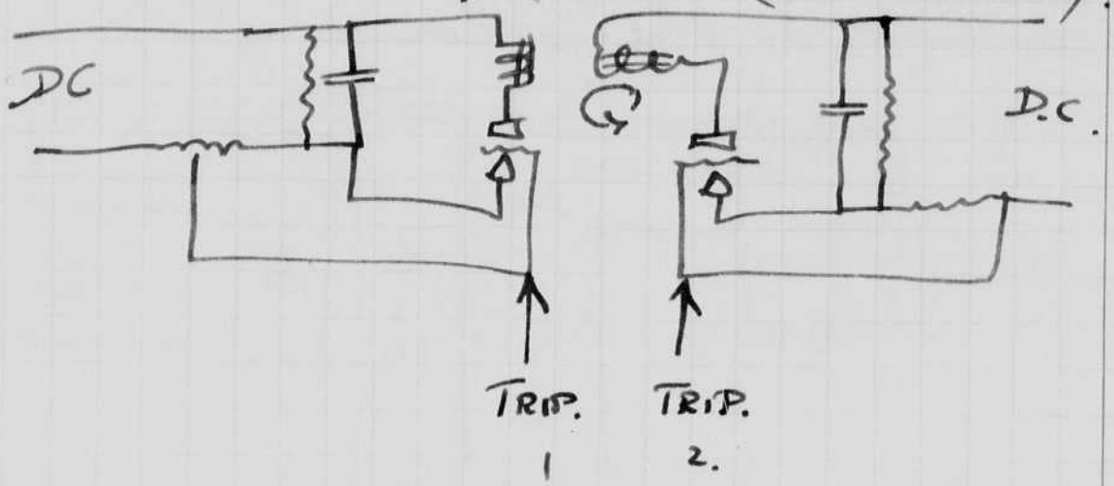
The above was wired up this afternoon Bliss and I took it over to the Forest laboratory and tried it out on some magnetic specimens that were there. It worked satisfactory. tomorrow Bliss is going to make a box and cables for the apparatus.

Borden was in this afternoon and we discussed inverter circuit for use in Hardy's color analyzer. I suggested the use of two single thyratrons to produce pulses of current to start the motor instead of the use of a.c. two pulses 180 degrees apart should give a rotation and the direction should be

determined by the ~~direction~~ relative firing time of the tubes.



2ϕ. motor (Induction).



June 11. 1936.

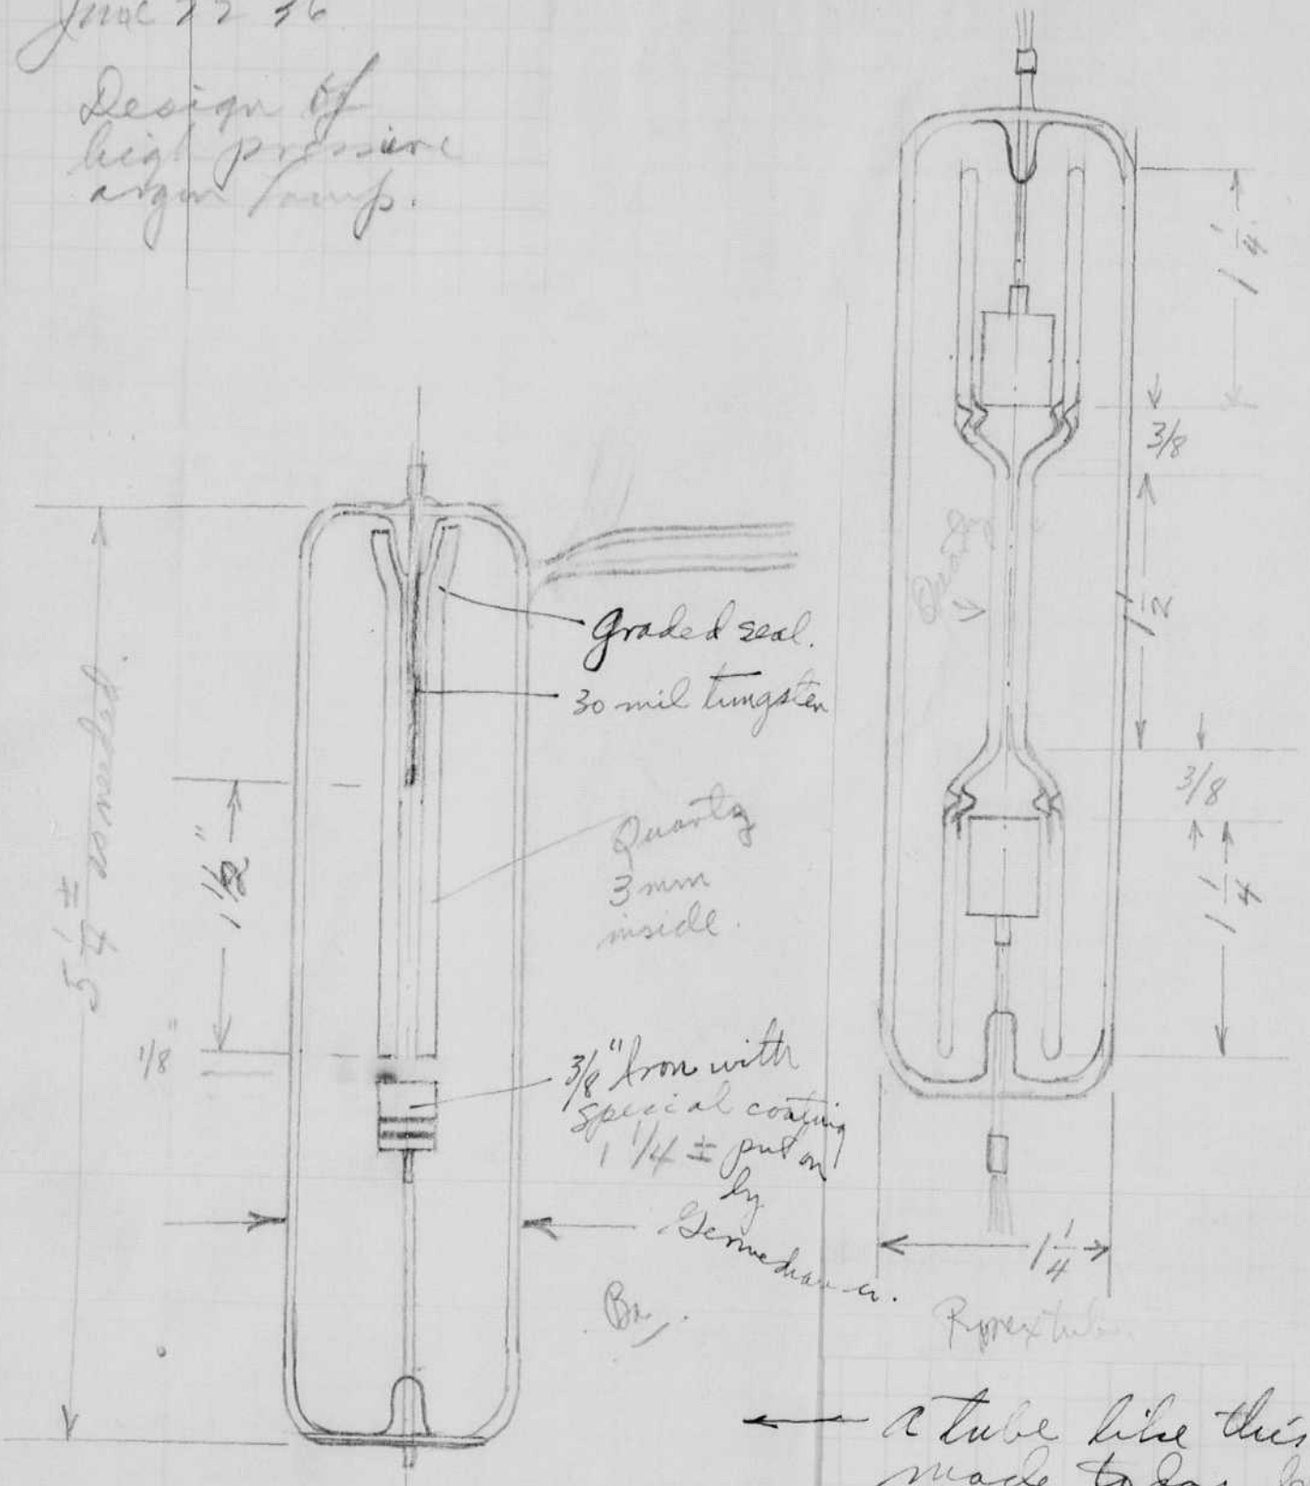
Design of high pressure argon lamp.



← A tube like this was made today by Mr. Waymouth.

A. Baked 1 hour 400° C±.
B. Bombarded 10 min ±.
C. Filled with argon at atmospheric pressure and run with 2 mf 3500 Ω 1400 volts also 1/2 mf.
D. Pumped out and filled with argon 20 cm.

GENERAL RADIO COMPANY

TYPE 631-P1 STROBOTRON
(Neon-Filled)

Main Use	Stroboscopic Light or Relay
Number of Electrodes	4
Cathode Type	Cold Cathode with Cathode Spot

Typical Load Characteristics

Anode Voltage (max)	350
Anode Voltage (min)	110
Maximum Inverse Anode Voltage	350
*Average Anode Current Milliamperes (max)	50 to 100
**Instantaneous Anode Current Amperes (max)	250
***Instantaneous Anode Current Amperes (min)	5 approximately
Average Tube Drop, Volts	
Glow Discharge	75
Arc Discharge	20 approximately

Typical Starting Characteristics

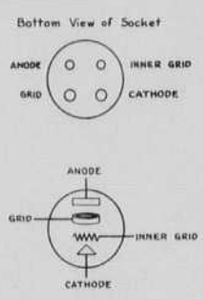
The Strobotron is started by causing a glow discharge between the grids. Either grid may be used as a control grid, the other grid being appropriately biased.

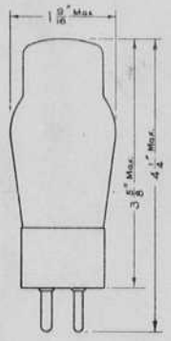
With Inner Grid at Cathode Potential

Starting Voltage, Grid Positive	110 to 120
Starting Voltage, Grid Negative	115 to 125
Grid Current Milliamperes (max)	1

* Rating is determined by heating and varies with peak and duty cycle.
** Surge obtained from condenser discharge, up to 12 mfd. at 250 volts.
*** Minimum current required to start cathode spot.

Socket Connections

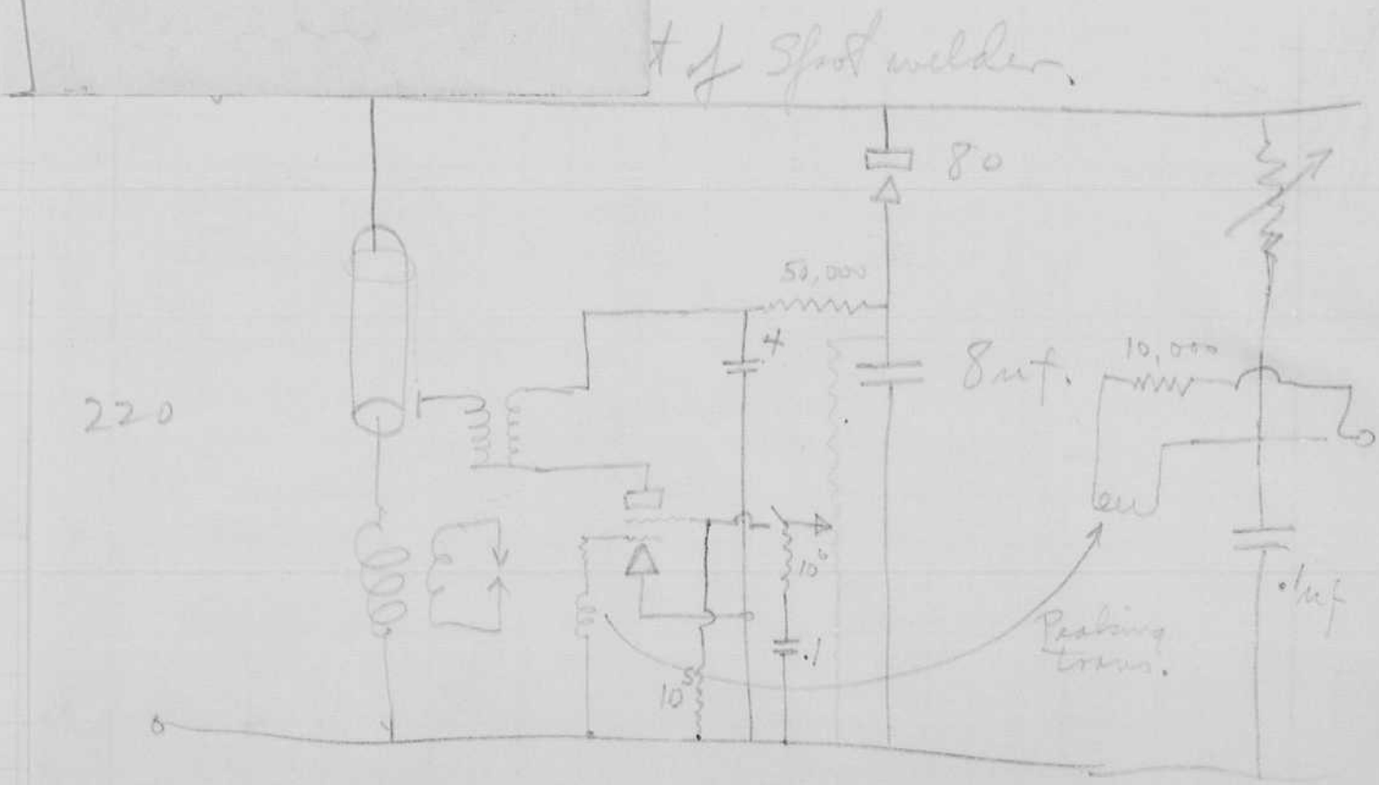




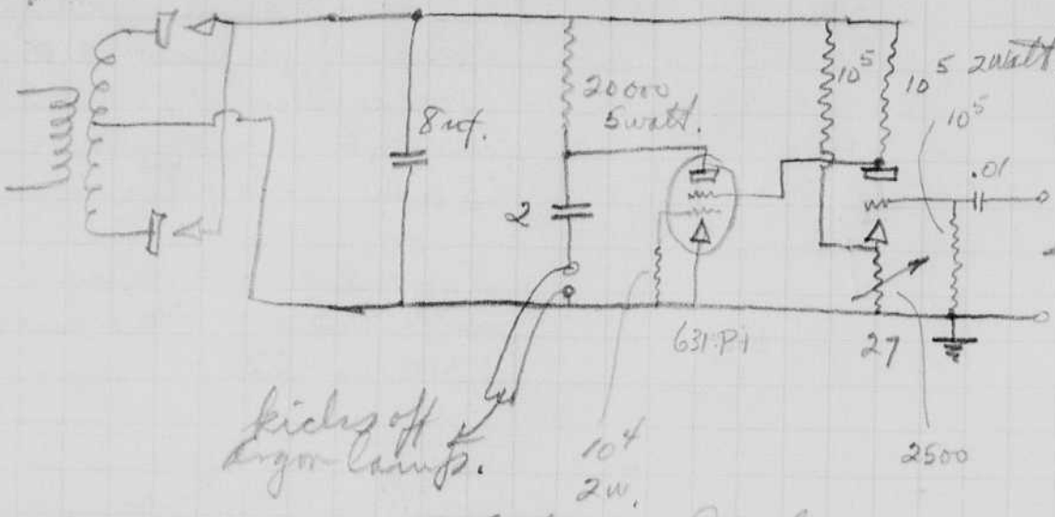
Form 427-A

The lamp shown on the preceding page runs ok at 1200 cycles 1½ mf. 400 ohms. charging resistor on the 3 kw outfit.

It holds over when run with 0.5 mf 800 ohms at 2500 volts.



June 24, 1936
H. E. Edgerton.



Circuit suggested to Dick Evans for use in the knee sorting machine in the Physics department.

June 24 cont'd. Yesterday Bliss finished the temporary setup (to be) of page 22) and tested it. He used 20 microfarads of capacity. The E.R. tests showed 1300 amps peak. A five foot lead (concentric cable) showed no decrease in the peak current. This means that all the inductance is in the condensers.

We have ordered some new condensers from the Cornell Dublier co which should be here soon. They will have less internal inductance, we hope.

Prof Defrenza was in this morning and asked for two more units same as shown on page 20.

Dick Taylor was down and I gave him two stroboscopes for experimental use on the new Integraph.

Swinish came in and I gave him two stroboscopes. He is going to Missouri University next year to be a Prof. in the Physics Dept.

I worked with Davarine all afternoon taking movies of sounding 1/200 sec 1200 volts (3 kw) 1.25 mf. 400 lumens per sq ft of 3.2 neg film Bond & H2O.

Alvin Blake

(1)

(1) $R = .07\,\omega$ on speed control.

Δ = 1 cm to point where tube begins to oscillate very fast.

δ = 3 mm after this point.

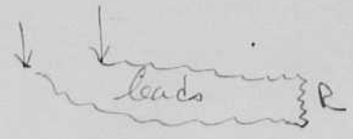
$V_\Delta = 58$ } on cathode ray tube.

$V_\delta = 18$

$I_\Delta = 830$ amps slow

$I_\delta = 260$ amps fast.

(2)



Concentric cable.
about 5 ft long.

$R = .07$

Δ = 7 mm

δ = 2 mm

$V_\Delta = 42$

$V_\delta = 12$

$I_\Delta = 600$ amps

$I_\delta = 170$ amps

Other conditions same as above.

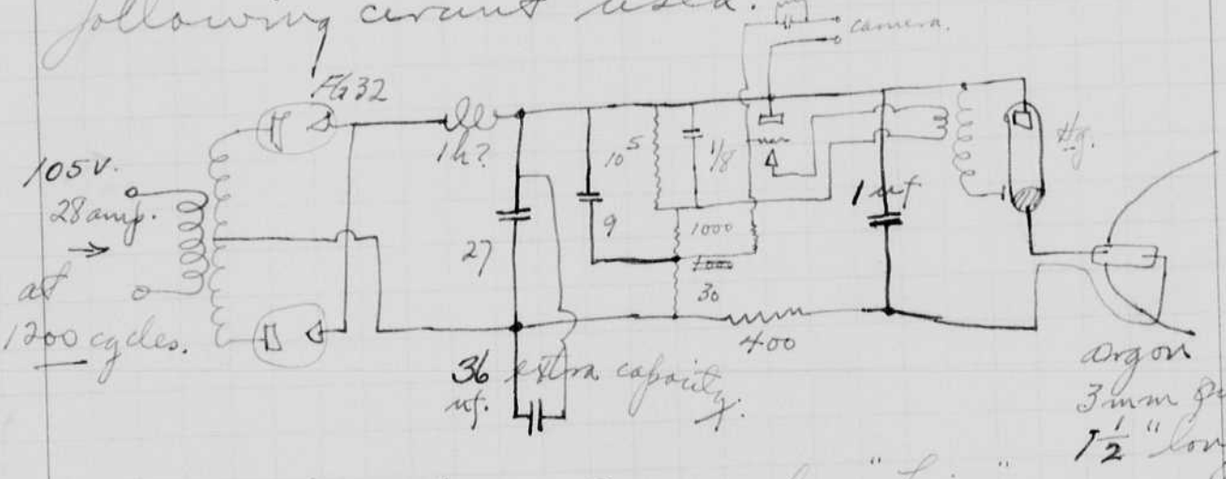
Measured by
Philip Bliss

July 2 1936

H. E. Edgerton.

The high-current surge generator described on page 20 and built by Bliss for Defreest was given to him last week and he at once sent it to Chicago for use. Two more are being built and will be delivered next week. The last two are quite different than the first as far as appearance is concerned. The new ones will be in a wooden cabinet with a cover like a meter.

I spent considerable time last week getting ready for a trip to Mrs. Lawrence Webster's home in Holderness N. H. To take photographs of humming birds in action. The three kw outfit was taken and the following circuit used.



Camera lens at f 2 Summar lens "Leica".
Regular negative Par speed film.

For single pictures a 12 mf condenser was connected in parallel with the 1 mf condenser and the 400 ohm resistor increased to 4000 ohms.

Grier went with me on the trip and we shot about 1000 ft of film (35 mm) and 3½ dozen of 9x12 cm verichrome single photographs. We left N. Y. at 10 Monday morning and arrived there about 3. in the afternoon. Returned the next day. Mr. & Mrs. Webster entertained us royally.

I spent yesterday and today processing film. The stills were ok but the movies were

not very good. The movies taken outside were ~~pictures~~ ing due to the fact that the bird flew away too quick. The movies taken through the windows were dim and not in focus? If we go back again, a white back ground should be put back of the object being photographed. The feathers of the bird do not photograph very well.

Nottingham has been trying out the spot welder using a strobotron and a Hg tube. He is trying to get a multiple cycle welder as well as a controlled half cycle welder.

Dick Taylor was down discussing the use of strobotrons in the new differential analyzer. Gemmeshausen spent some time with him this afternoon going over the proposed circuits.

Javarine and I spent several hours together today editing the high speed motion pictures of steel quenched in water, oil, and in brine. He is going to write titles and complete the reel for showing next fall at the meeting of the metallurgy society.

High pressure argon lamp.

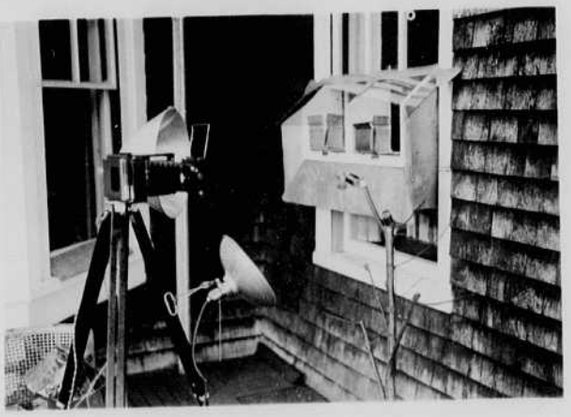
July 10 1936
D & Edgerton

My father & mother were here from July 3 to today. My sister Mary Ellen and her two boys came also from Summit N.J. Dad and I spent Monday July 6 at the Acousti Products Co. taking Golf Pictures for Mr. Young. 61 photos taken

Herbert G. Drier with the apparatus that we took to Holderness N.H.



Set up for single photos note bird in center.

Mr. & Mrs. Lawrence Webster

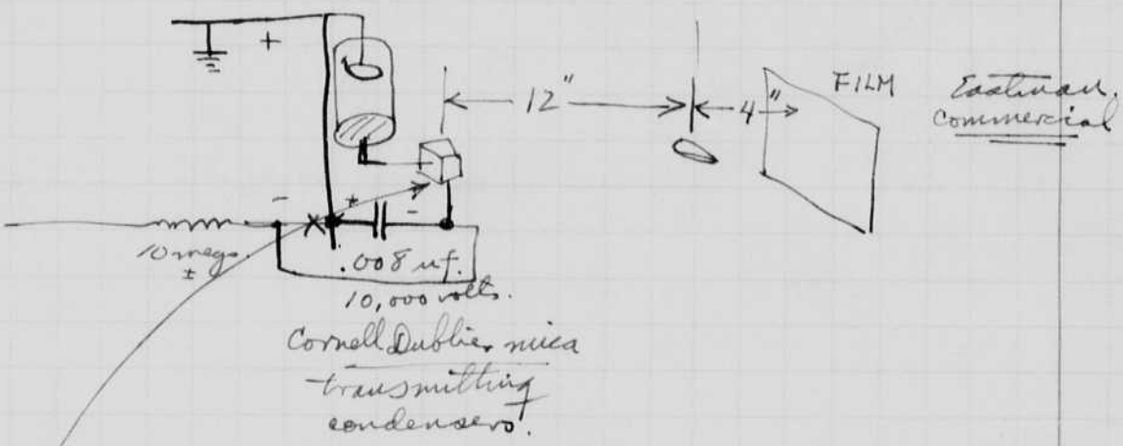
Mrs. Lawrence Webster with two humming birds.

July 11, 1936.

Herb Grier was married today to Winifred Davis.

Zerneshausen and Stook shadow spark photographs on July 9 in the evening. Regular .30 caliber service ammunition was used in a regular army rifle. Some of the photographs were taken with the bullet going through a #18 gage aluminum sheet.

The spark was timed with a rochelle salt piezo electric crystal energized by the sound wave that followed the bullet. The amplifier circuit is shown on page 7 and page 8 of this notebook. Other details are shown below.



Spark gap in a lava block. 1 mm hole or slightly less. aluminum wires for electrodes.

The negatives were thin. More capacity or more voltage should be used.

Cont.

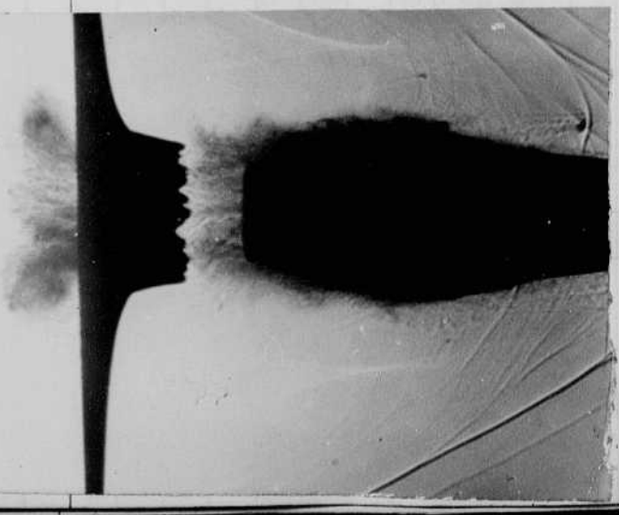
I made a tube as shown on page 36 with about 2" between electrodes. Heated, pumped out, filled with H_2 at 1 cm, ran with glow discharge to both electrodes as cathodes, filled with argon at 1 atmos and sealed off.

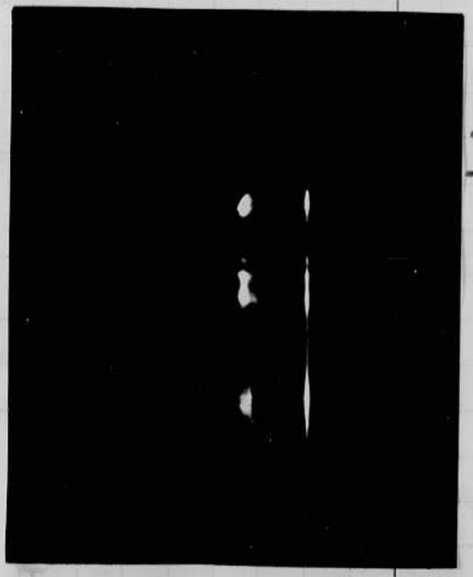
This tube would just about hold off 10,000 volts. In fact it did after firing a few times. A red or yellow deposit flows up the long tube for holding the gap when it fires. After firing the other way to strip it off the tube blew out on the cathode side.

tube repaired and only gave about 3 flashes before it blew and again.

July 20 1936. Cont experiments. Rebuilt argon lamp as described above but with 8 mm O.D. pyrex glass. It broke again but this was due to a strain due to over heating while on exhaust. Repaired and repumped. 1 cm of hydrogen was put in with 1 atmosphere of argon.

7. Argon lamp. 0.5 mf 10,000 v. 3600 RPM.
8. Ditto but with slit (too narrow or not lined up).
9. Argon lamp (1 cm H_2) — Ditto.





July 22 1936.

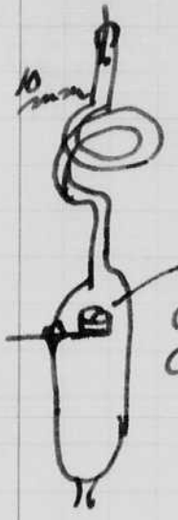
Bez.

took several photos of .30 cal with tube with 1 cm of H2 and 1 atmos of argon. Only one came out and it was timed late. The tube finally blew up.

Another tube was made yesterday of slightly larger tubing and with a slightly longer path. 3 cm of Hg was put in it. This tube holds off the 10,000 or 12000 from the power pack. It trips ok by a spark on the cathode leg.

This morning I talked to Mr Reed of the Watertown Arsenal about the spark photographs. He is writing up a report.

I built a tube for the movie outfit that looks like the following.



An oxide coated cathode was used which Semerhow brought from the Hygrade Co.

It was treated electrically by running an arc discharge through the tube. The CO2 was pumped out.

20 cm of argon was put in the tube and it trips ok. in the 3 kw movie outfit at 700/sec 2 uf. 1200 V ± 400 Volts. Also did run up to 1200 cycles with the same setup. The cathode got red hot and may be too small?

a second tube exactly the same except for cathode was made. It was hard to start when on the pump. Filled with 10 cm argon and tried in the movie outfit, but did not start. Repumped to 4/100 cm and then held over night. Repumped and filled to 5 cm but operation was still

Cont'd

I made a tube as shown on page 36 with about 2" between electrodes. Heated, pumped out, filled with H_2 at 1 cm, ran with glow discharge to both electrodes as cathodes, filled with argon at 1 atmos and sealed off.

This tube would just about hold off 10,000 volts. In fact it did after firing a few times. A red or yellow deposit grows up the glass tube for holding the gap when it fires. After firing the apparatus to strip it off the tube blew out on the cathode side.

Tube repaired and only gave about 3 flashes before it blew out again.

Aug 12 1936
DeEdgerton.

On Sat Aug 8 Grier and I took 400 ft of moving at 600/sec of a fish cutting machine at the General Sea Foods corp. on the fish pier. Mr. Brown was developing the machine. Also took 12 snaps with 20 mf 400 volts.

Mac-B. co made me a tube with a 6? mm quartz spiral inside. Also a manifold and pressure manometer for a new all argon system.

← Baked - and sealed with Bombarder. Sealed off with 5 cm. At this pressure the tube will work Ok. as a stroboscope on 1000 volts using an outside spark for excitation.

Tried on movie camera 3 new out fit. 400 ohms 2.25 mf. Worked ok at 600 cycles at first, then started holdover. Works fine at 200 and 150! The pressure should probably be higher.

With 800 ohms, however, and 1.25 mf. it runs ok.

Tube retubulated and repumped to fill to higher pressure. Filled to 10 cm argon. Works ok now 400 ohms 2.25 mf 600 cycles. No holdover. A few misses when started first time.

Operation data 4.25 mf. 200 ohms. 850 volts. (1000 volts ac input to work)
600 cycles 2.3 amps. 33.2 amps.
99% at set.

Holdover with (1200 cycles) 2.25 mf 200 ohms.
(3.5 amps dc current).

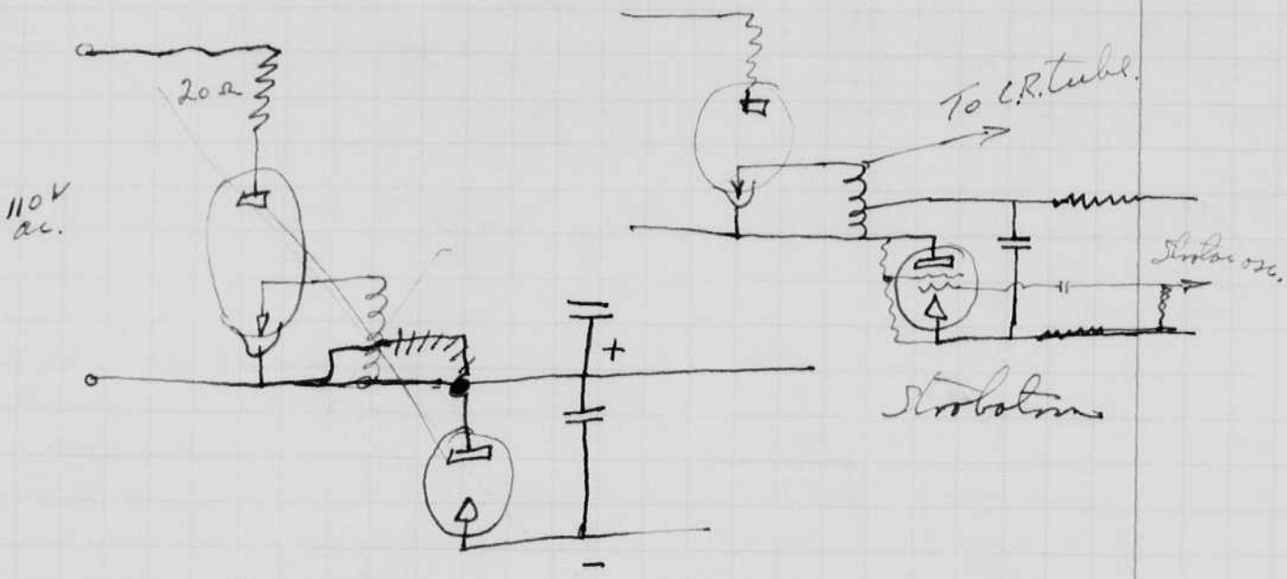
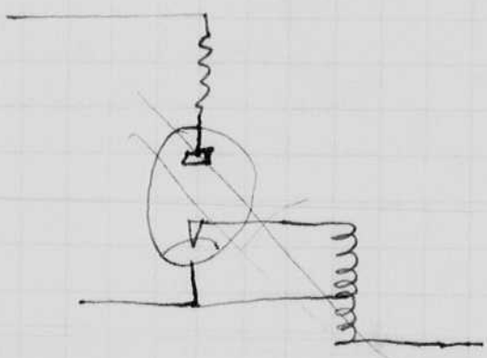
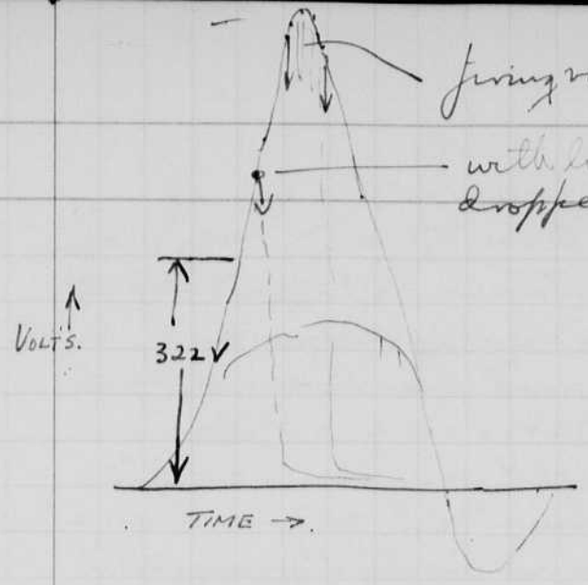
H. H. Edgerton. Cathode ray meas. of Ignitron starting characteristics

Gennesharsen experimented this a.m. on Ignitron setup. He left at 3 and I continued experiments.





The plate voltage of one of the strobotac oscillator plates was used as a sweep voltage. Used on the most sensitive plates of the C.R. tube FP 54 5000 volts plate voltage. (2.9 ma on meter).



firing voltage varied about this much

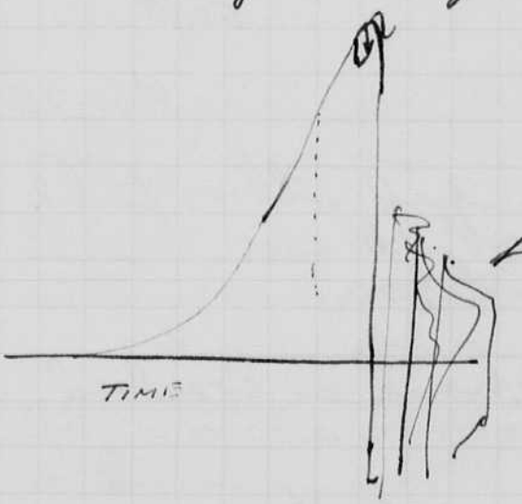
with load on the firing voltage sometimes dropped this low

$115 \times 2 \times \sqrt{2} = 230.4$

920
230
322

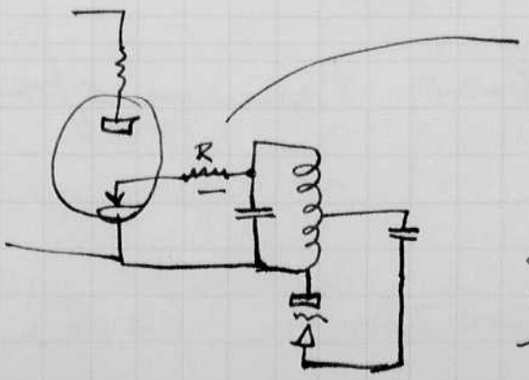
The ignitron was tipped so that the crystal was further immersed in the mercury. The extra load before firing reduced the voltage peak about 20% and firing (without the main ignitron load) became irregular. Fired sometime at 500 volts. Fires better when load is on.

An .03 mf condenser was put across the secondary. Does not change waveform much but delays voltage rise.



firing stuff here now.

I believe this is due to the condenser discharge through the starter over shooting. Reversing brings a positive voltage which fires at a lower potential.



Tried out. 10 ohms is enough to stop oscillations shown above, but 100 ohms operation is ok. Operation is nice and steady. Also seems to fire at lower voltage. 300-400 with out load.

Oct 15 1936

H. E. Edgerton.

A.I.E.E. meeting last night. St Louis (G.E. vapor lamp co) gave the first talk. Nottingham attended with me.

Two new tubes have just been made by Mr. Wagninger. The type is the same as shown on page 44. The active light source is a 2" length of quartz tubing, about 0.4 cm in diameter. It is coiled into a circle and into the anode and cathode at each end.

Oct 16, 36

Tube pumped and filled with 10 cm argon. The other had a leaky seal.
Holds over with 400 ohms 2.25 mf.
Repumped and filled to 18 cm.
Runs ok 350 ohms 2.25 mf. 600
Holds over " 1.25 " 1200
Spits " 2.25 " 1200.

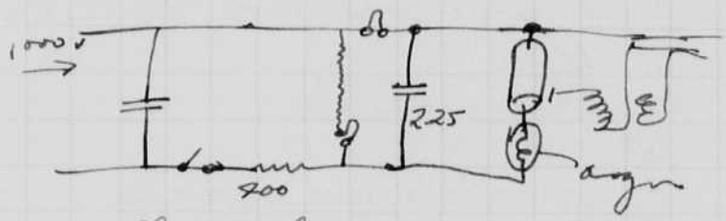
reduce the pressure? Should more
volts be used? Figure out experiment
to show up trouble such as.



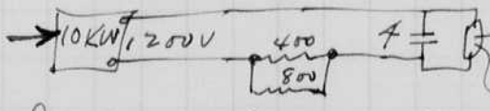
oscillograph

Oct 28, 1936. Pumped tube argon with 2" length of 4 mm
and sealed off with 6 cm argon.

Result a rather grainy tube and filled
with 20 cm argon.

Shipped some after running.

Retubulated and repumped. Treated with
following circuit



The electrodes and guard became red hot.
Sealed off with 1/4 cm argon.

This tube worked in a satisfactory
manner at 1200 flashes per second
in the above circuit for a few
series of flashes (1 sec in duration).
Then it started to miss even at 600
cycles/second. The gas when excited by the

spark coil appears orange tinged showing impurities.

This tube has an acting length of about 3 or 3½ inches of 7.9 mm (inside diameter) quartz tubing. The ends are 11/16" in diameter

A new tube was ordered today with a 1½ inch length of 3 mm I.D. Quartz tubing as the acting length and with tungsten electrodes.

Mr. Tucker is going to work with Prof Hauser as a special research assistant. I had lunch today with them and discussed problems to be done.

Oct. 30. 1936. H. E. Edgerton.

That tube mentioned above was made and pumped but the seal broke. It runs ok with 1200 volts at one atmosphere. 20 mf was used. Very bright.

Nov. 5, 1936.

Showed new reel (just assembled) last night to the M.I.T. faculty club.

Yesterday two men from the Jenstell Co were here, Mr. Driggs, F. H. and ?
Discussed auto ignition system.

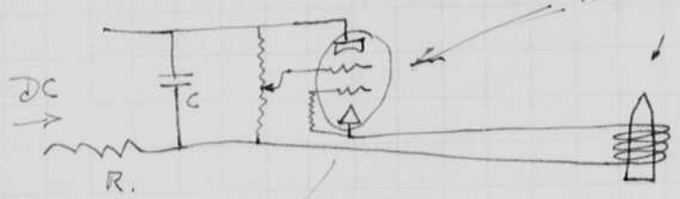
Morning and all day Nov. 11 at R.C.A. Radiotron in Harrison N. J. Saw B J Thompson, Dr Miller Mr. Ritter? Dr Chase Shaw. Dave Langmuir, Schaeffer Wagner and others. Showed the High speed movies at 7:30 p m to a large group.

Nov 13 1936

H. E. Edgerton.

Apparatus for removing
metalic particles from
runners and from apparatus.

A condenser discharge through a coil and a rectifier produces a very strong force on a magnetic particle because of the large momentary magnetic field. The discharge can be periodic using circuits which have been used in stroboscopic work. The strobotron circuit which we developed for Defrost should serve satisfactorily also.



Strobotron,
Thyratron or large Hg lamp.

The series of jerks excited by the magnet should produce a strong force on the magnetic particle, more so than possible with a steady pull by a dc coil.

I also believe that the size and cost of the apparatus is low enough to make it available to many doctors and to small manufacturing companies.

Explained to Me by H. E. Edgerton
Nov 14, 1936 Kenneth J. Germeshausen

This above was discussed at lunch with Horton on Jan 20 in Walker when Germs and I were there.
Jan 21 KJG

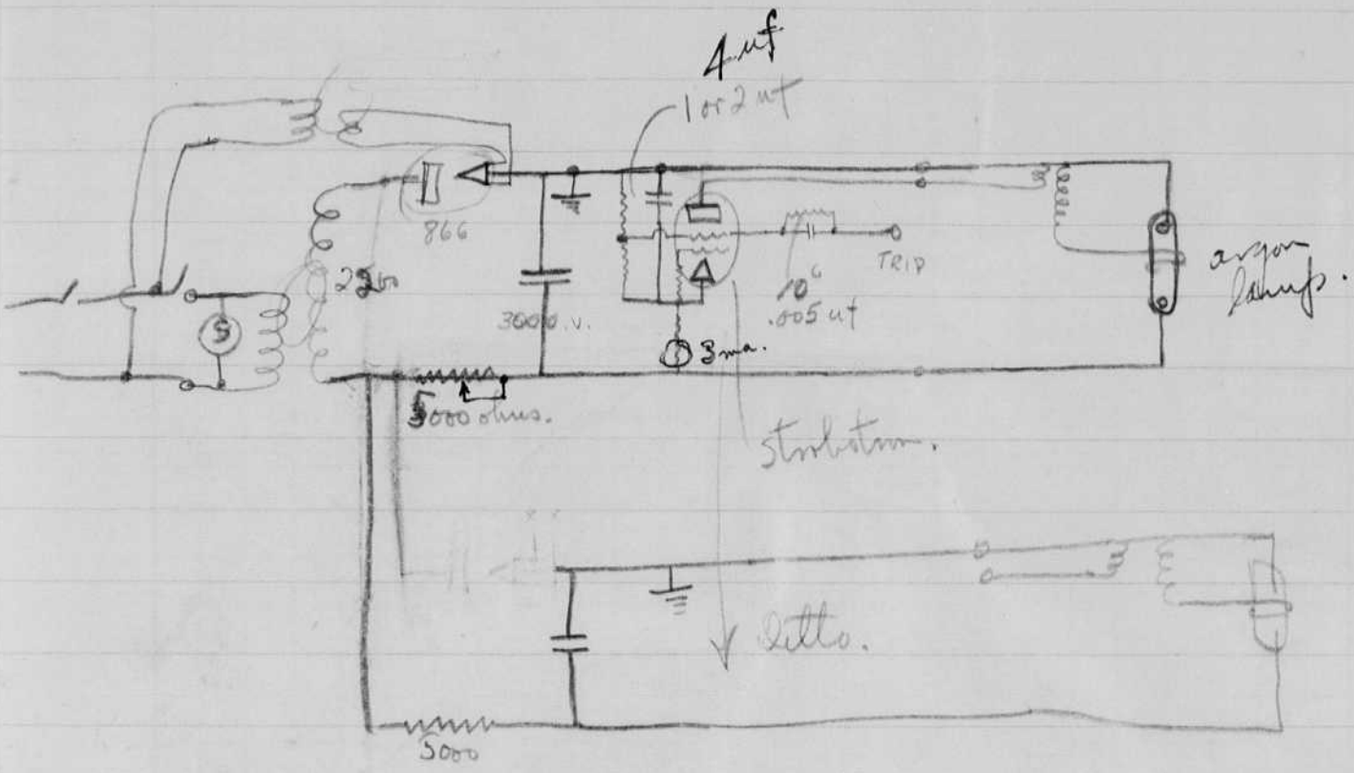
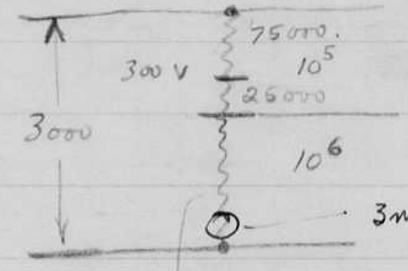
Plans for new Spark-Argon apparatus

Drawn on Nov 7 1936,

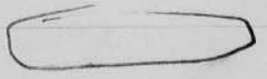




.003000

3000 3000 / 10^6 1 watt.

5 200,000 ohm, 2 watt resistors.



20 mf. 3000 volts.

Nov 15 1936
H. E. Edgerton.

Last night I worked with Mooney on his thesis problem after having him out to dinner. We had a .30 caliber rifle from the R.O.T.C. and some armor piercing ammunition. The experiments were not entirely successful due to the fact that the amplifier was microphonic. Also I accidently shot through one of Mooney's trip coils.

A student named Townsend is going to work with the mercury tube rectifier using the external grid to start the action with no sources of e.m.f. in the plate circuit: I outlined the problem to him at some length about two weeks ago and listed a series of experiments for him to do. He is now reading Mueller's theses and also a laboratory report by Howard.

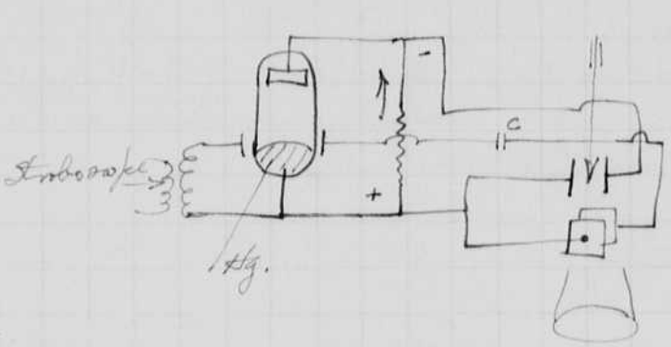
He is setting up a thyratron oscillator to put high voltage on the grid of the Hg tube and will work in the high-voltage room 10-180?.

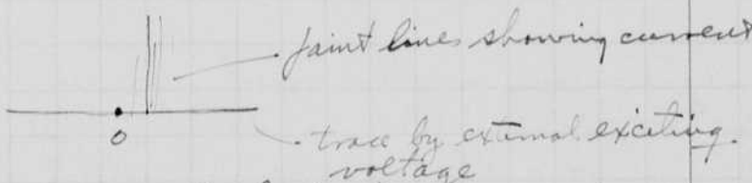
As I recall the experiments discussed are:

1. Freeze the liquid Hg at the bottom of the tube to see if the emission current stops.
2. Vary the gas pressure, argon, neon etc to find effect.
3. Vary the anode cathode spacing.
4. Vary the cathode area. (glass-Hg contact distance)
5. Vary the glass thickness.
6. Investigate the effect of frequency of the disturbing voltage to note if wave motions of Hg are important.
7. Put DC on external grid and shake tube with variable frequency.
8. Find regulation etc of tube, i.e. volt-amps. char.

9. Try to build tube with other metal than Hg.
(this may not work with solid metal - see 1.)

10. Investigate instantaneous currents from anode-cathode and correlate with grid voltage. A series of experiments were made last year on this, but I could not find record when talking to Townsend last week. As I recall, the external exciting voltage was put on one set of plates and the current (drop in a resistor) across the others.





This experiment indicated that the current was erratic and that it came at the zero or slightly positive of the a.c. on the external grid.

11. We also discussed possible regulating schemes for keeping constant current or constant voltage on the output by controlling the external exciting voltage by the output.

Nov 21 1936
H E Edgerton

H T Day, New York, came on thurs Nov 19. for the spark machine 3 mf 16000 volt.

On Nov 17 took 2½ doz 9×12 gas Tucker photos of Jans for Peters (GE job). Carter helped by this while learning how to run the camera.

Studied Jans again today with Peters and took more photos. See GE Book.

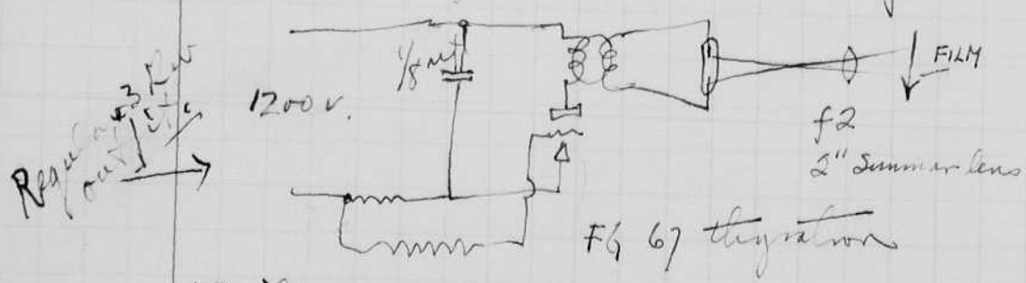
Nov. 26, 1936.

Prints made of photos (Peters) made on the 21st. These show some new results and peters wants some more motion pictures.

I set up the Motion picture apparatus last monday Nov. 23. d. Ran through a film on the G.E. Jan (narrow blade) on the 24th.

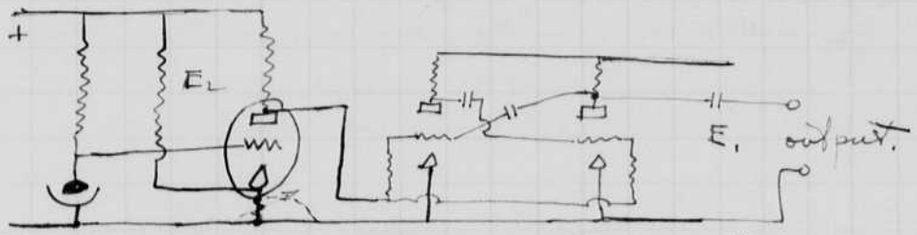
Prof. Henry has been busy inventing circuits to use in a photoelectric engraving machine. He has arranged for us to build a light source for the thing. A few tubes have already been built as below

This is filled with argon at 15 cm. the circuit for flashing is the following.

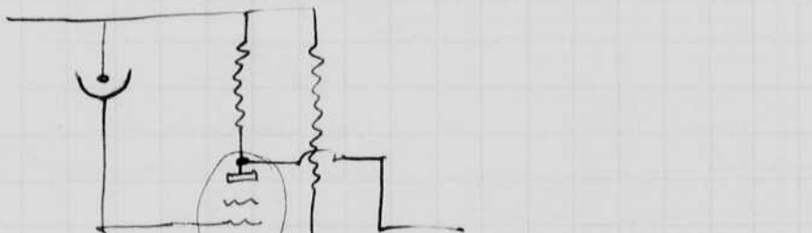


Tests run at 150 cycles/sec. Sound recording film. Exposure ok at 1:1 reduction size.

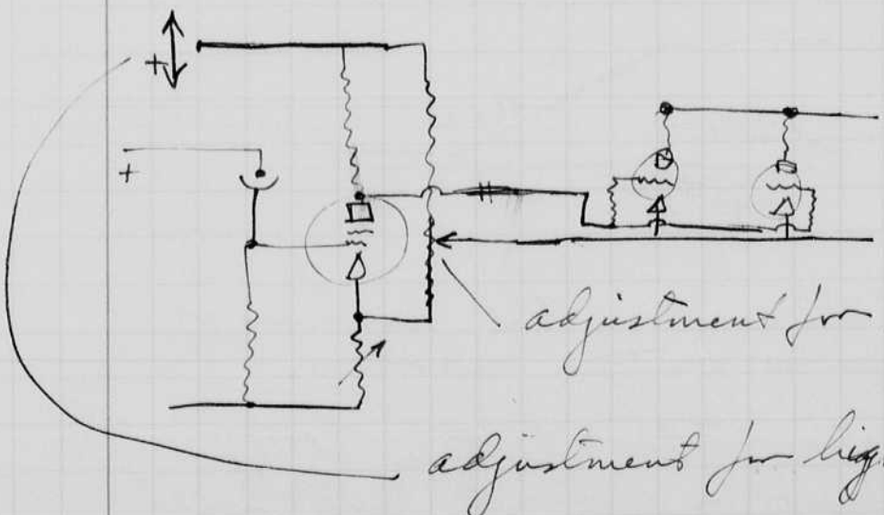
Varney discussed his ideas with me at some length yesterday and called me on the phone twice today about additional methods of getting the photocell to put dots on the film. Variable spacing of black dots for the light parts of the engraving but light dots for the dark. The method of doing this with a photocell and flashing lamps may be bothersome.



this circuit produces a frequency that decreases with light.

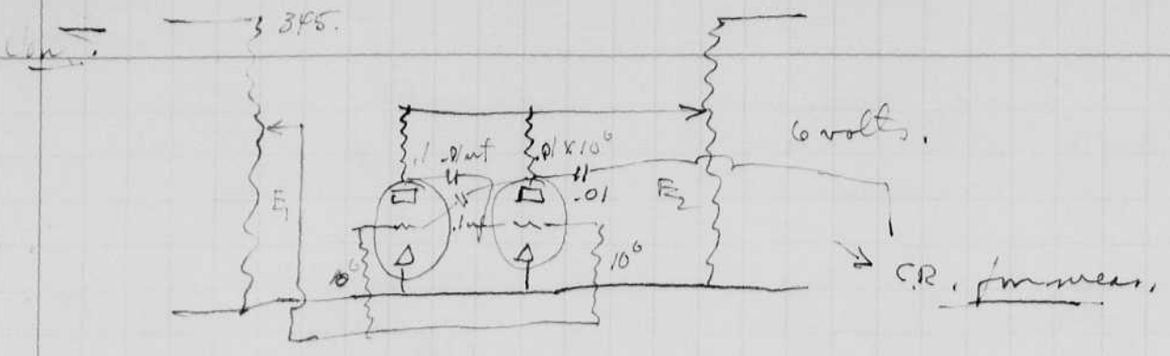


this circuit produces a frequency that increases with light.



2000
10

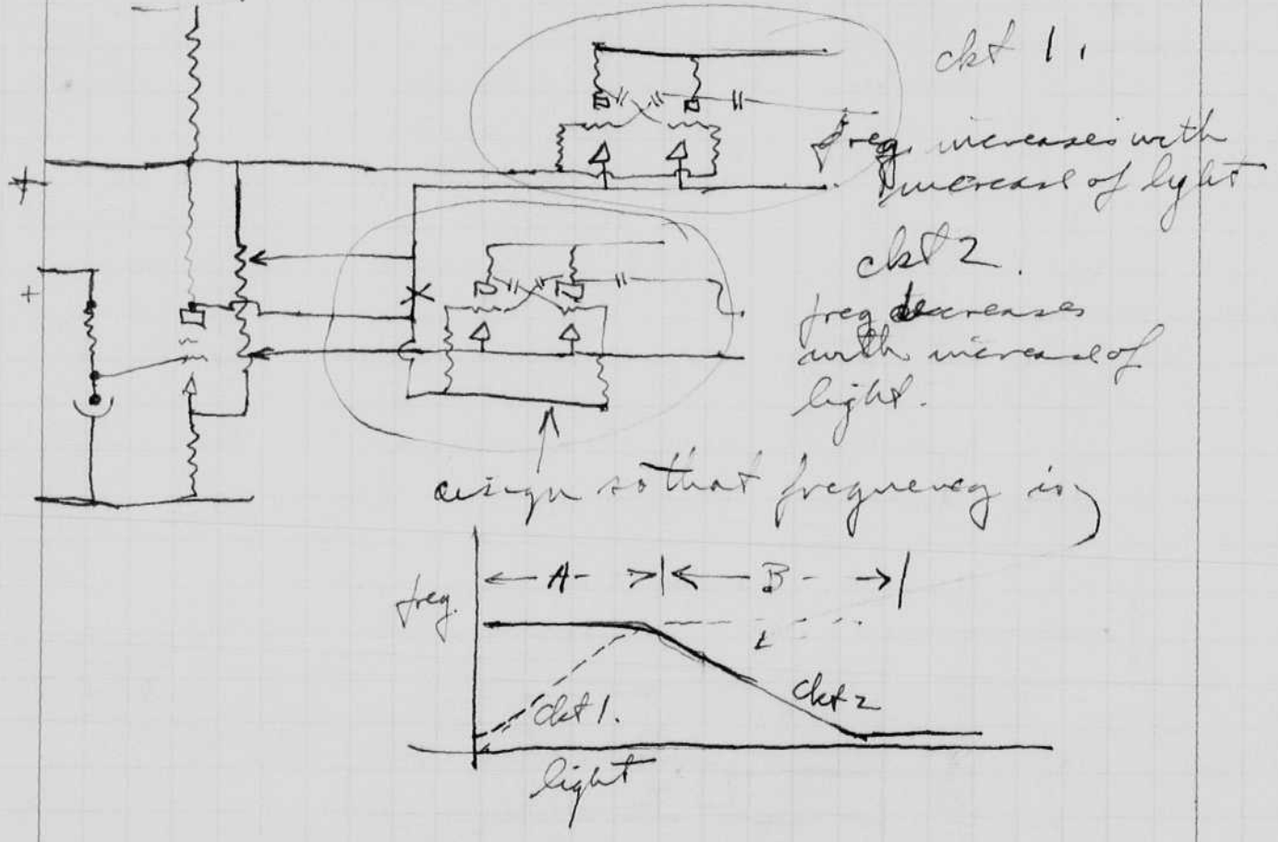
200-1.



$f_{reg} = \frac{E_1}{E_2} \frac{1}{2RC}$?

$= \frac{E_1}{E_2} \frac{1}{2.2 \times 10^{-6} \times 10^6} = \frac{E_1}{E_2} 5.$

$\frac{2000}{5} \times 5 = 2000$ cycles.



Circuit 2 will control the flashing of the Strobowipe lamp that puts on the marks.

Circuit 1 will prevent the starting of the strobo wiper lamp in region A but will be in operation in region B.

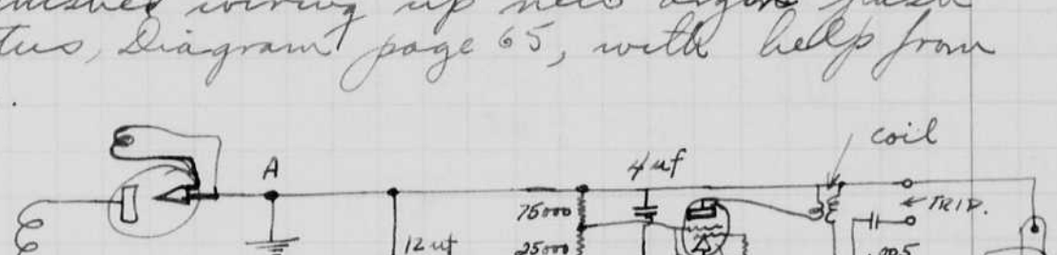
Nov. 30, 1936.

Hardy came in on Saturday Nov. 28. and explained at some length the circuits that he told me about on Thanks giving over the phone. Germeshausen is building a special glow lamps for this job for producing puts!

Martin of Allis Chalmers co was here today to deliver a lecture upon mercury arc rectifiers.

I worked this afternoon with Mr. Cheney of the M. E. Department, trying to take photographs of a pelton wheel. Difficulty was experienced in photographing through wet glass.

Finished wiring up new argon flash apparatus, Diagram page 65, with help from Kiethley.



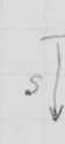
Circuit right of A.B. repeated for several

Dec. 2, 1930.
Harold E. Edgerton.

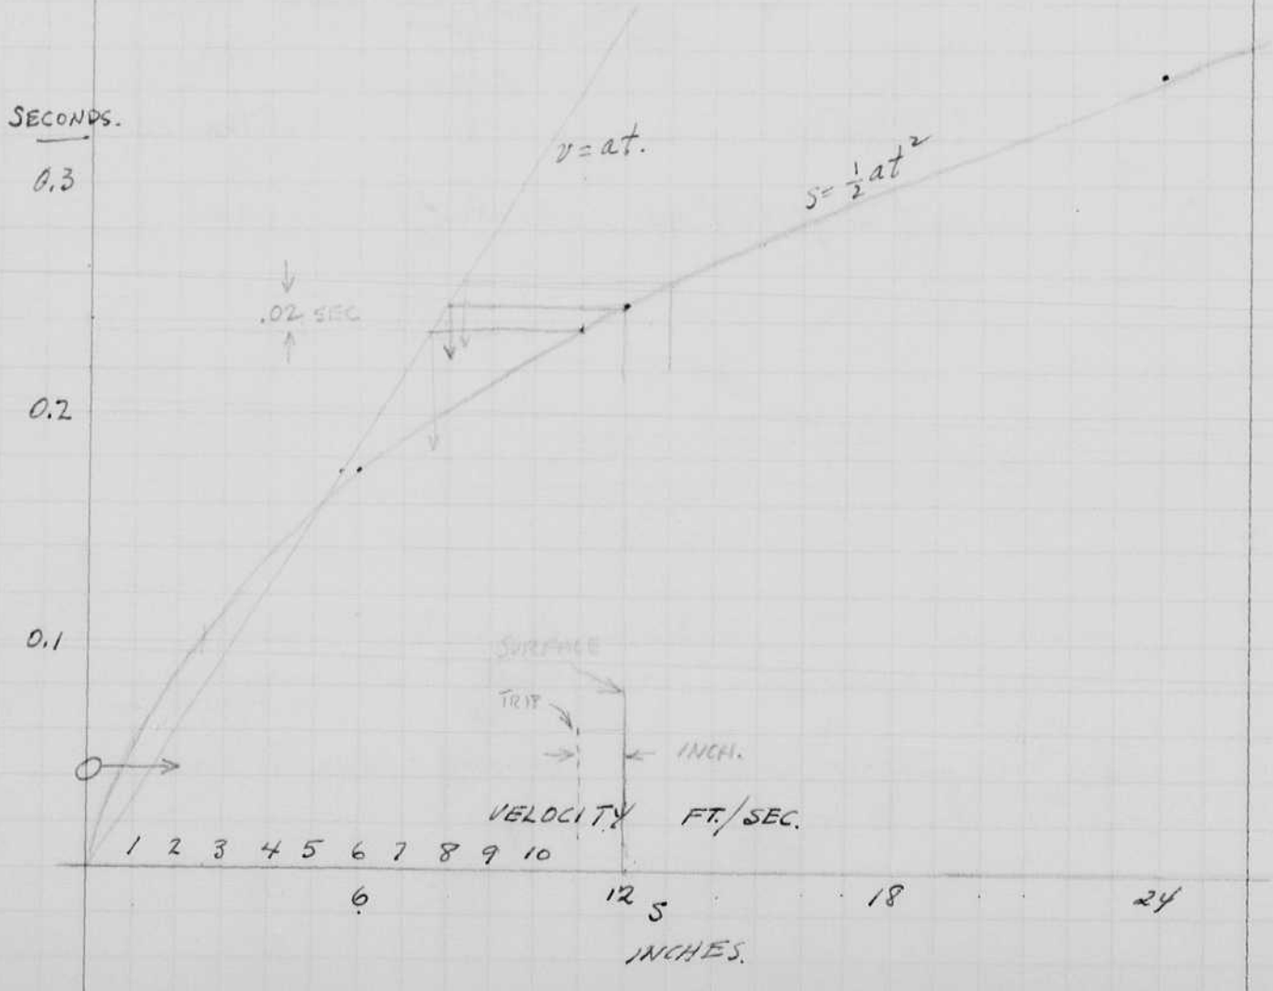
I worked last night with a student named Kiethley taking photographs of milk drops. Leica camera used f 18.5 new Spark machine used diagram on page 71. For some of the photographs the lamp was in a reflector. In others it was not. Distance to tube from drop about 4 to 6 inches. Photocell trip of light beam used. These pictures look good.

Mr. Pettingill and Mr. ? came in today and I demonstrated the 548 Stroboscope.

Calculations for time delay apparatus to be used in photographing splashes.



$$s = \frac{1}{2} a t^2.$$



Dec. 6, 1936.
H. E. Edgerton.

Set up water dropper on the crane in the Dynamo Laboratory and took closeup photos of the drops after they had fallen 24 ft 10 inches. The Leiga camera was used. $\frac{13\frac{1}{2}}{16} = \frac{27}{32}$
with lens extension so that
1 3/8 inches on the film
was of 27/32 on the subject.

$$\text{magnification} = \frac{1\frac{3}{8}}{27/32} = \frac{11}{8}\,\frac{4}{27} = \frac{44}{27}.$$

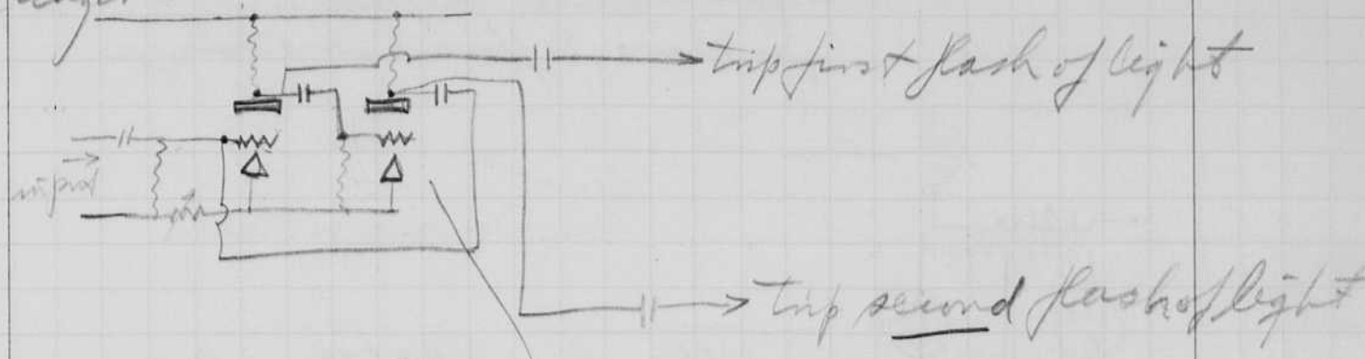
Dec 7, 1936 Time delayed flashes.
H E Edgerton

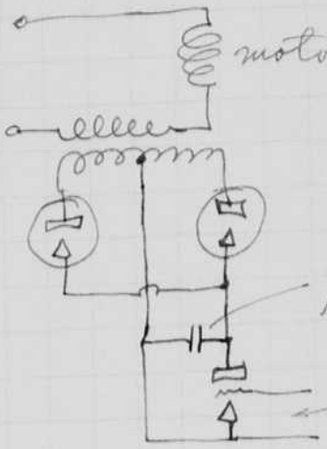


This method should be useful for measuring velocity. It will give two exposures on the same film at a known interval of time apart. The method can be stretched to more than two photographs

The second tube above may need a capacity from plate to cathode in order to slow up the voltage build up rate when tube no 1 snaps on, to prevent the early flashing of lamp no 2.

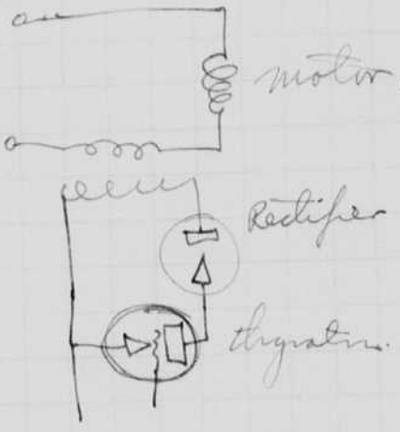
Dec. 11, 1936
Harold E. Edgerton

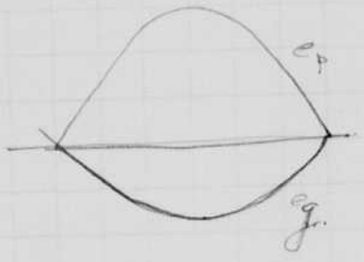
Motor control method
for new Differential Analyzer.

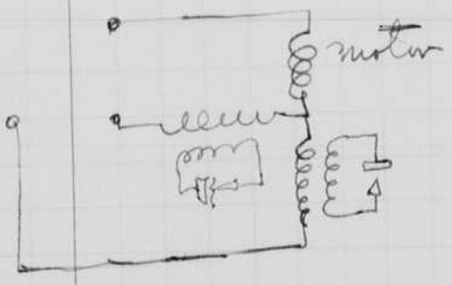


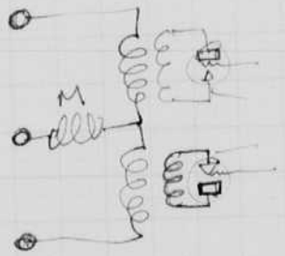
possibly not needed if thyratron is ~~needed~~ used. Condenser is required with thyratron.

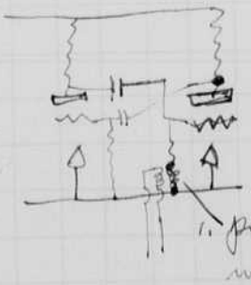
Ideal Starting Characteristic







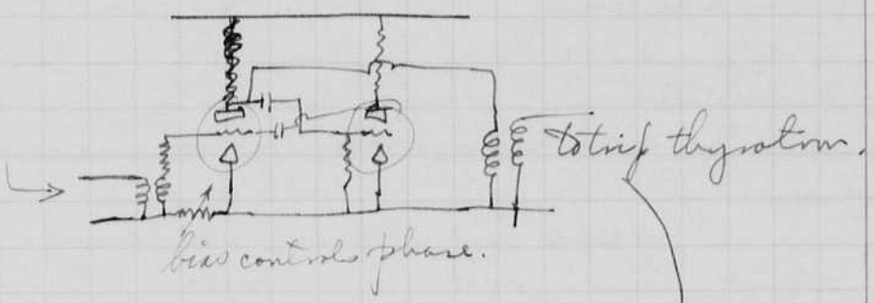


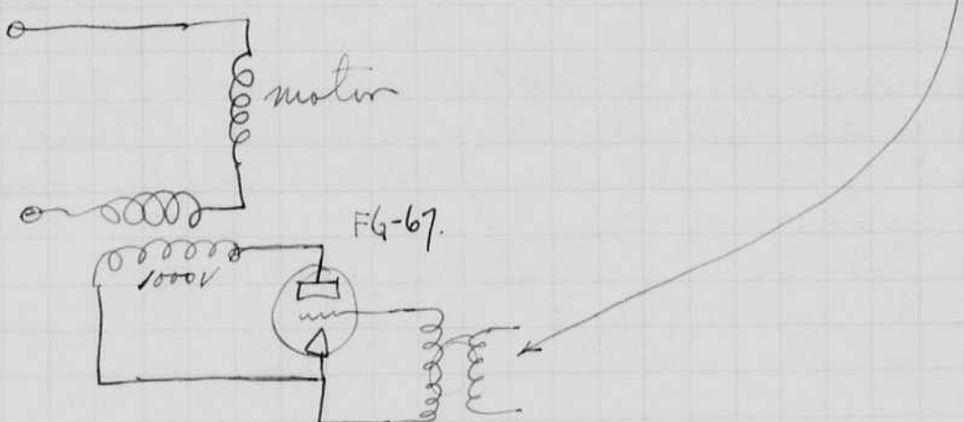


1. put bias in series with input to grid.
2. Use R and C to ~~run~~ lower than 60 so that control will be ~~more than~~ 180 degrees or

3. Introduce 90° phase angle into the input.

control part of cycle.



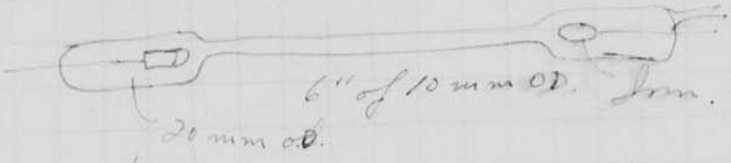


thyratron with positive starting characteristic

After drawing the above in the evening I went over to Sam Caldwell's house and discussed the above scheme with him and with Jaeger. Jaeger plans to hook up multipulse to apparatus to dribble a mercury thyratron.

Dec 12 1936

I had two tubes made of the following design.



Pumped and filled with argon 1 atmosphere. 3 mf 15000 volts blew them both up! Shattered the glass completely into small parts. Mr. Popkin and Price saw this.

I used the same seals and electrodes in a tube about 14 mm OD. 9 or 10" long. Again 1 atmosphere of argon. Works ok.

Camera setups. of Price & of Popkin. Light in cylindrical reflector 6" from object. Camera f 11 Verichrome film. exposure 0.2 s.

Dec 13 1936.

Spent all day with Kiethly taking photos of the drops in the elevator shaft. The dropper was on the elevator, dropping through a hole in the floor. Pictures were taken with the elevator at 5th 1st 2nd 3rd 4th 5th and 8th floor. The camera was at the level of the basement floor. A photocell method of tripping was used. From the 8th floor the drops were in a 8" circle. Two photos taken to get 2 pictures of drops!

The drops do not break up in falling this distance. Wt of drops about 0.9 grams.

H.E.Edg.
Dec. 14 1936

Germeshausen and I spent the afternoon at the Raytheon Co talking with Mr. Marshall about possibilities of cooperation with the strobotron and the circuits that we have developed principally for welding control. It may be possible to work out a method whereby we are also consultants for them in all engineering work and also receive a royalty for sale of strob tubes and other apparatus. Discussed Hg pool tubes with external bands with P. Spencer. Also saw Bertram after visiting the factory.

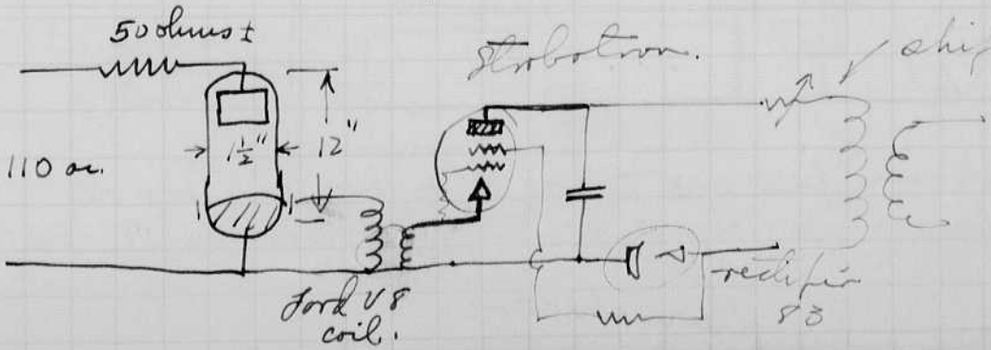
Dec 15 1936
H.E.Edgerton.

I spent the morning in Mr. Rines office with Mr. P. Friedman and Mr. O.H. Eschholz of the Westinghouse Company discussing the synchronous motor control system of angle switching. Invitation to visit Pittsburgh

Had supper at the home of Robley Evans and then took spark photos of Mr Lamie? hitting a table tennis ball. Newton Center.

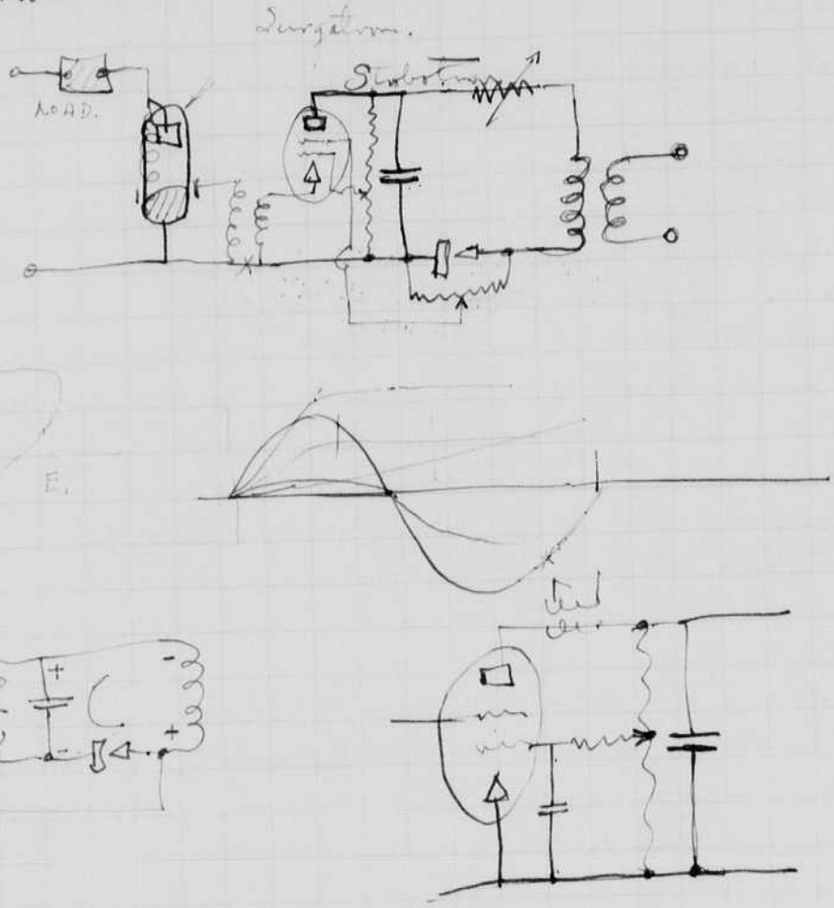
I talked to Jaeger and Caldwell again today about motor control schemes for speed control. The Hg pool type tube was discussed as a possibility for driving the motors instead of the tubes they are using. A Strobotron will also be needed to map on the Hg tube.

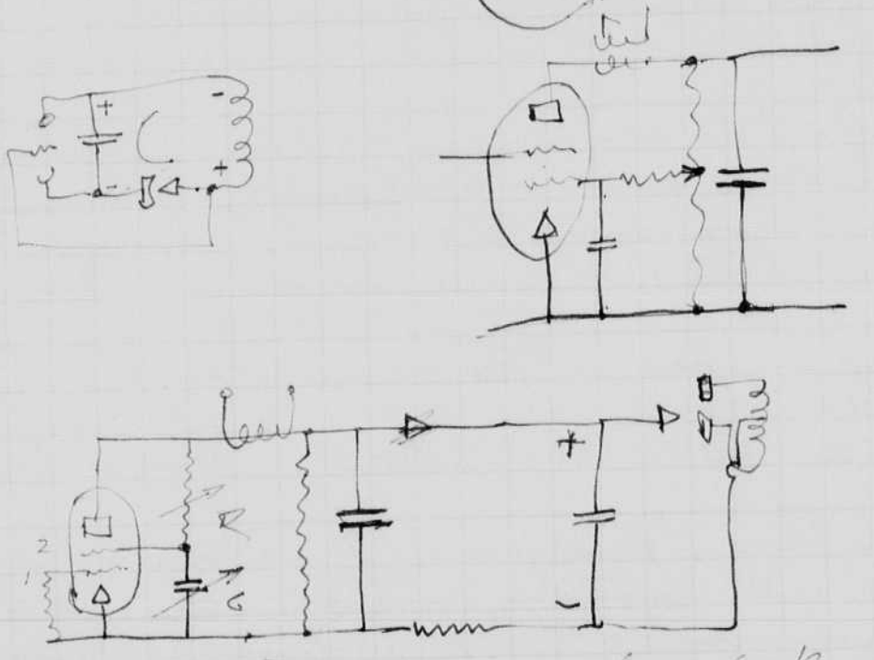
a Hg tube with Strobotron control has been on life test since Dec 11 1936 Days only.



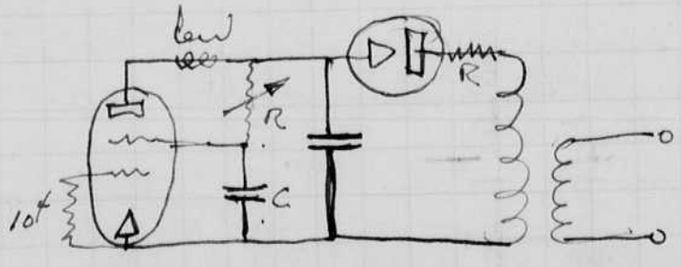
Dec. 12, 1936.
H. E. Edgerton

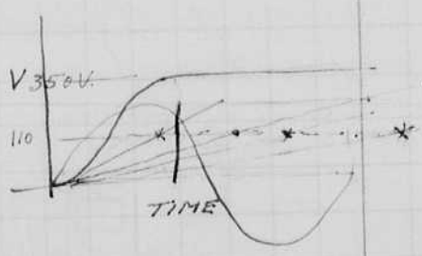
Phase shift control for Hg-Pool tubes.





Grid 2 voltage goes to zero at each flash due to arc condition in tube. Build up of voltage on grid 2 is determined by the RC combination indicated above.





Circuit Explained

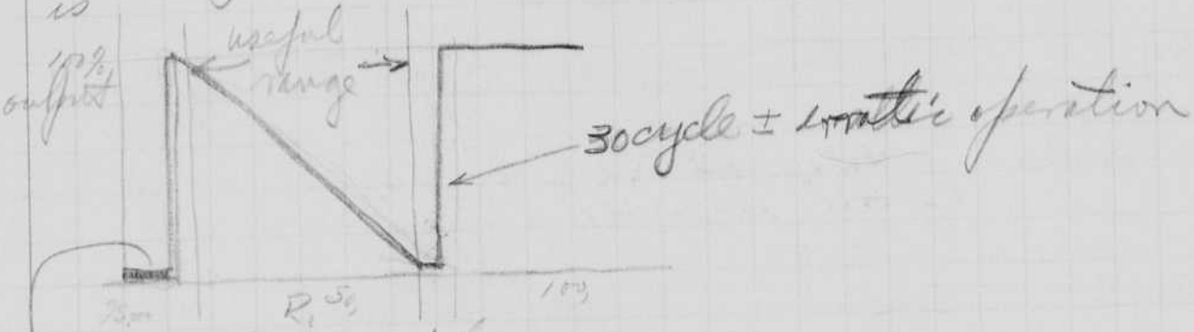
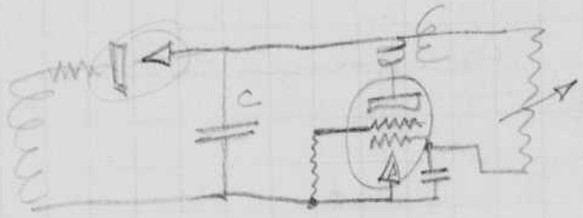
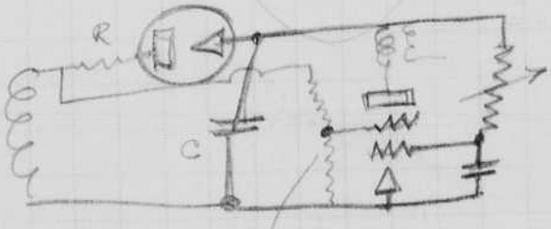
The circuit for phase control on page 83 has a disadvantage due to the form of the output curve vs Resistance, which is



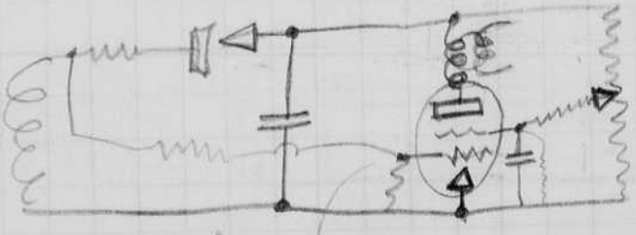
Control resistance off single shot tube gives before voltage is positive on Hg pool tube.



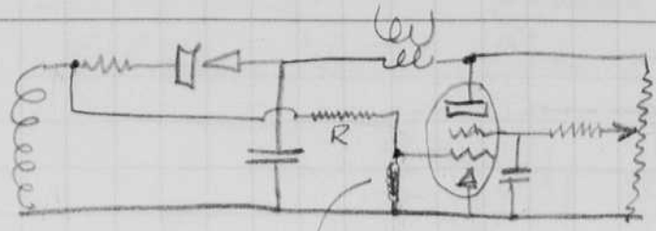
this may be steadied in operation.

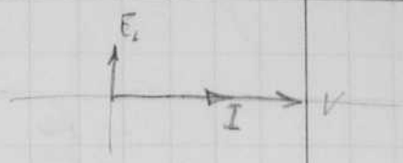


put ac on outer grid.

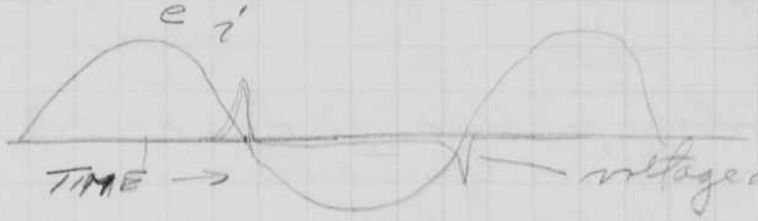


this probably will not be needed.

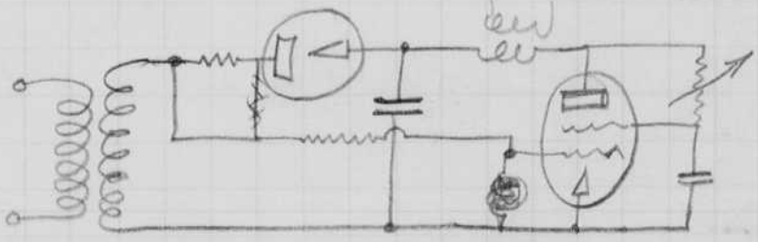




Saturated core reactor to produce a peaked voltage at the end of the cycle. Resistance R limits the flow of current through the choke

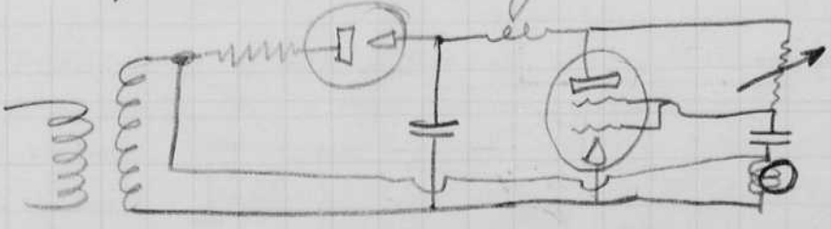


This peaked waveform will produce a negative surge of voltage on the inner grid and fire the thyratron at the zero of the cycle, making the operation positive in case the time constant is such as to not fire the tube. Overcomes the erratic operation mentioned on page 84.



It probably will also fire the first part of the cycle? Possibly not depending upon the magnitude of the peaked voltage and the voltage on the outer grid at the zero of the cycle.

Works ok also for three element tube.



Explained 12-17-36

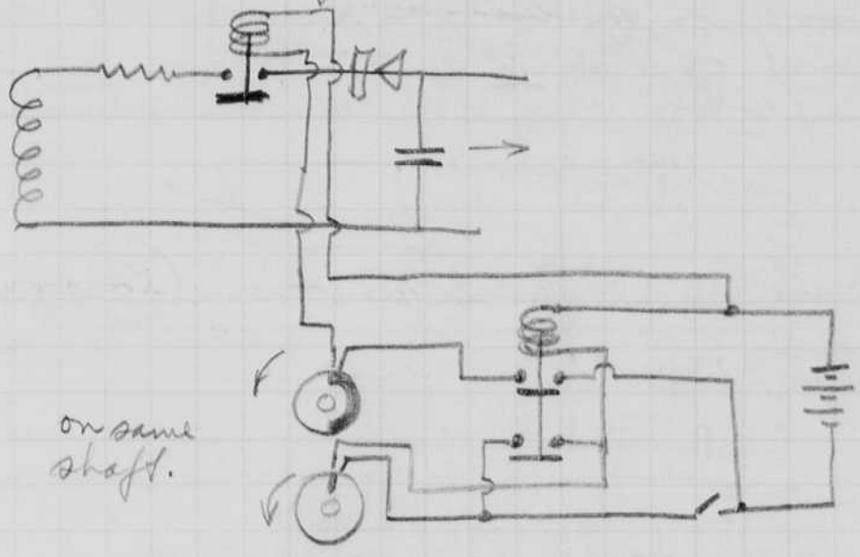
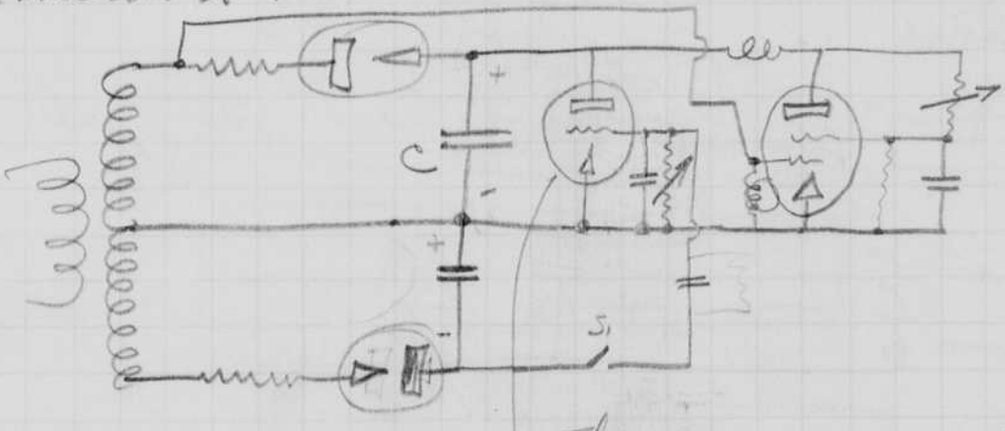
cont.

Redrawn sketch of same



3rd method.



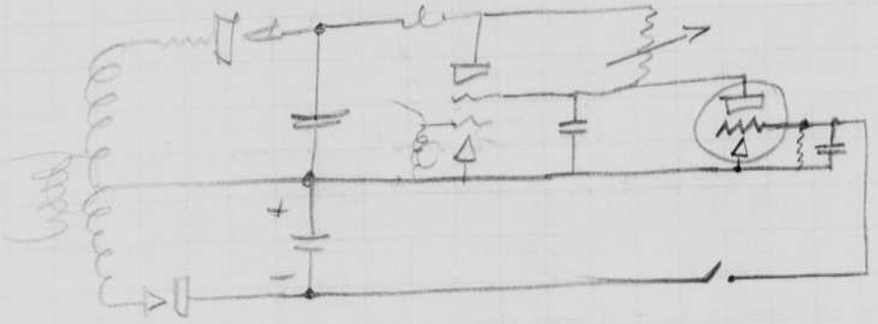
This is a vacuum tube that has zero potential on the grid when S1 is open.

The output of the condenser current is thereby shunted so that the stroboton does not fire.

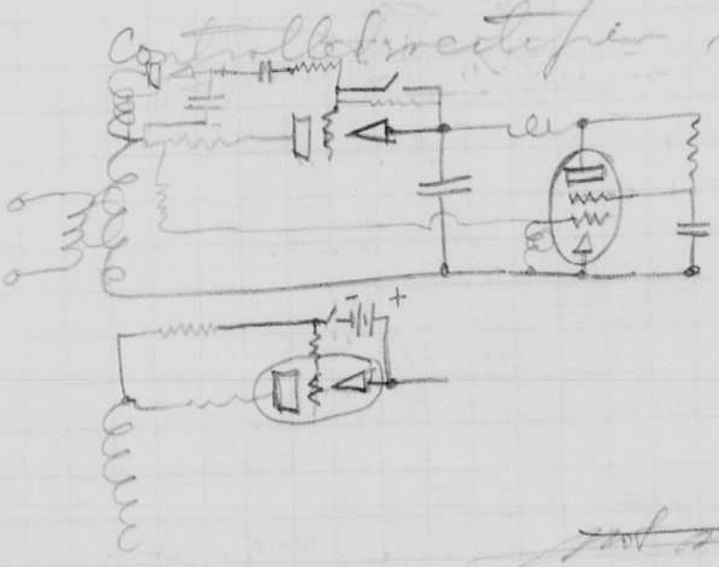
Closing the switch S1 puts a large negative bias on vac, triode and this takes off the heavy shunting plate current allowing the strobotron a chance to fire. The charge leaks from the grid condenser at a rate determined by the resistance shown across it. Eventually the vac triode again shunts the condenser and stops the strobotron.

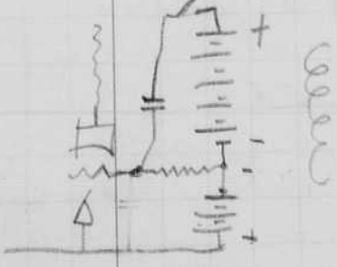
Dec 16 1936 Cont.

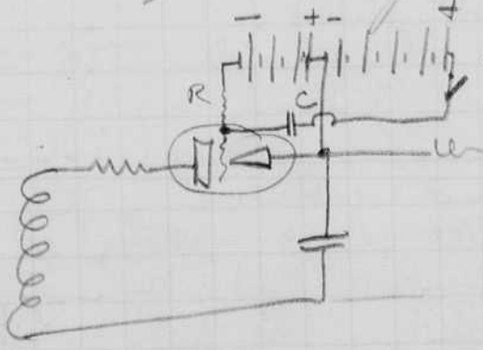
A modification would be to work a similar circuit in the grid of the strobotron & put a tube in the strobotron.



Operation same as previous page. If the triode passes out due to life it will turn the strobotron on all the time.

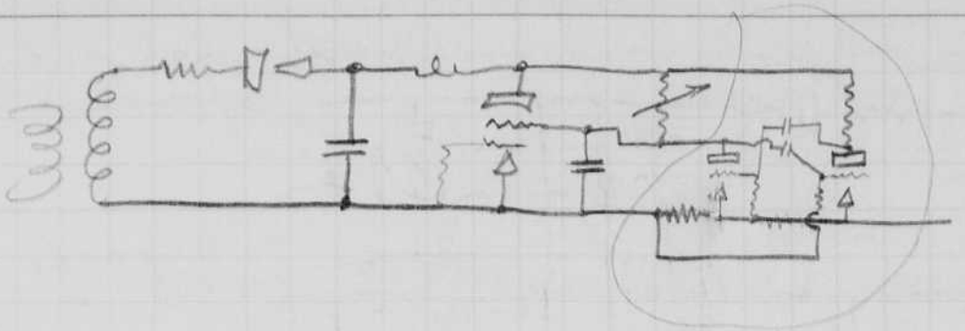




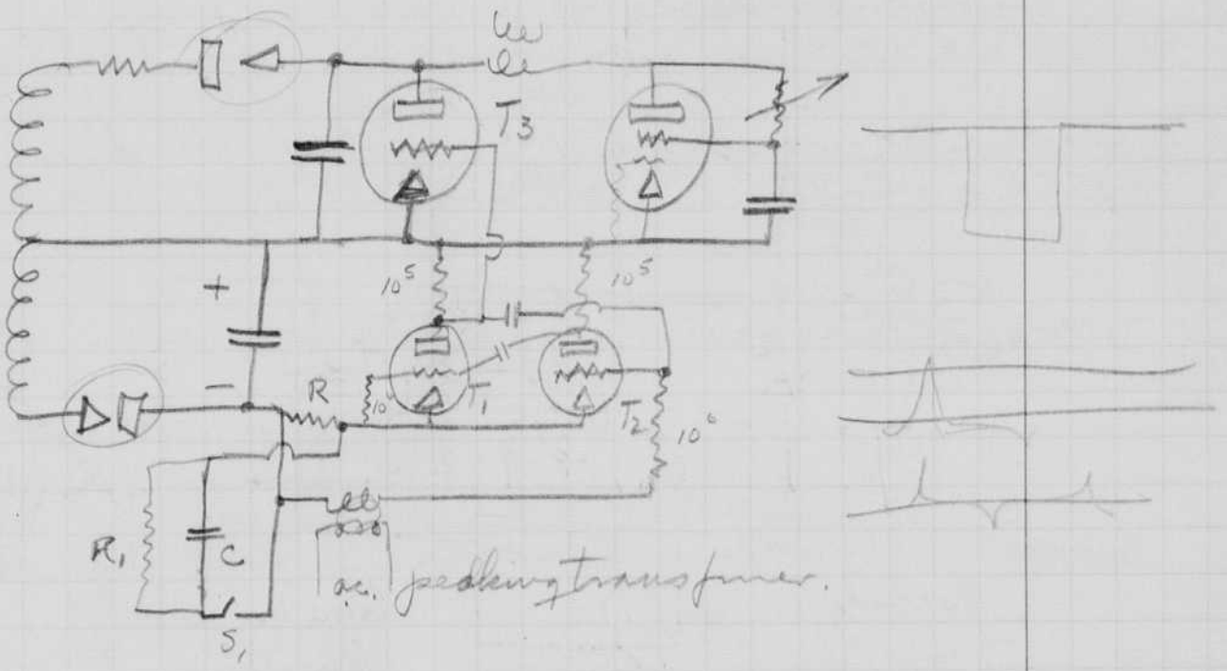


close switch puts + voltage on grid for certain length of time. depending on R.C.

Cont.



biased multivibrator to hold the circuit off for a definite time.



Close S_1 charges C from bias circuit thereby reducing bias to value nearer cut-off value, making it possible to turn on T_2 at the correct part of the ac cycle. Relaxation oscillator (one cycle) then results which puts zero bias on T_3 for a known time. C is charged in 1 cycle of the ac so that the relaxation oscillator does not operate to again. R_1 bleeds C when S_1 is open, preparing for the next flash.

The feeding transformer may not be needed in this type of circuit.

This circuit works ok for the full wave arrangement. Both triodes T_3 are given zero bias by the same multivibrator.

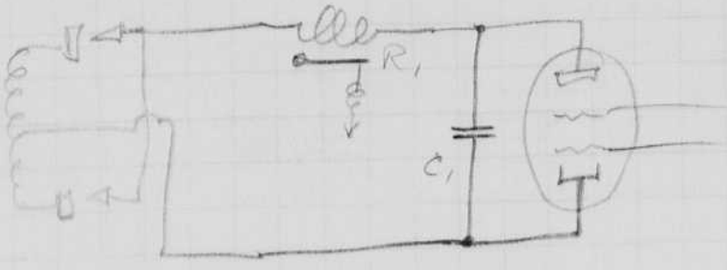
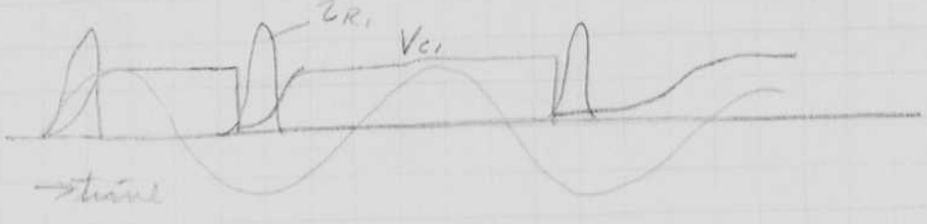
Synchronizing control.

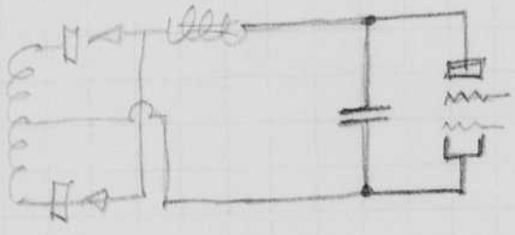
1. Ready to go instantly.
2. No tubes to operate while running (except field excitation in place of exciter by rectifier).
3. No extra brushes on motor shaft.
4. Minimum of apparatus on shaft.

The above strobotron circuit can be made frequency responsive by proper adjustment as follows. The Relay R_1 is held in by the charging current through its coil & the condenser C_1. This current comes in pulses from the rectifier tube T_2. By changing the spring on the relay that pulls it shut it can be made to operate on a miss of 1 or 2 or 3 cycles. The number of cycles missed depend upon the speed of the motor

and the width of the capacity electrode.





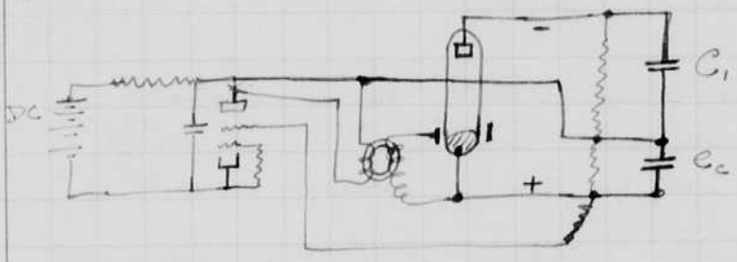


Dec. 22 1936 cont
H.E. Edgerton.

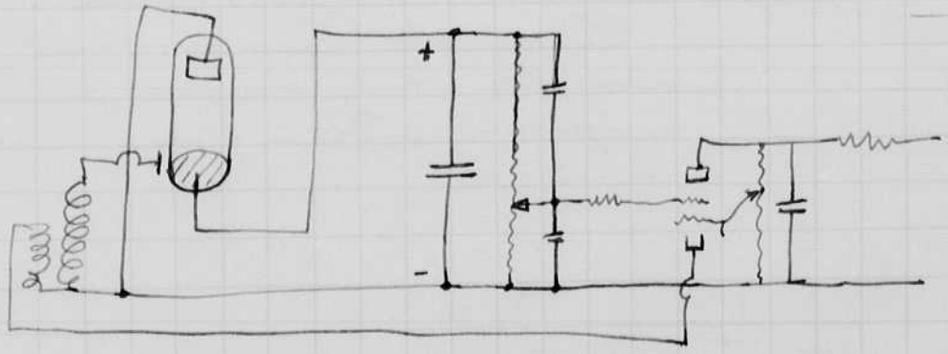
D.C. Power Supply from external Band Hg tubes.

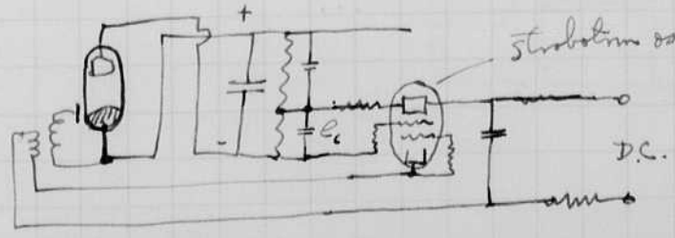
As has been described before, a high negative potential is found to exist upon the anode of a mercury-arc tube with an external band starter, excited with high voltage, (above 2000 or 3500 volts).

I have been thinking about circuits for regulating the output voltage. Such a circuit would be connected so as to keep either current or voltage constant or of a certain determined function of each other.



when as e_c becomes larger the strobotron fires at a slower rate and will finally stop oscillating. The charge going into the condenser C_1 is a function of the number of surges from the oscillator





The output voltage e_c controls the oscillation frequency.

grid currents in microamperes.

Jan 3, 1938
Harold E. Edgerton

I returned yesterday from a trip to Pittsburgh Atlantic City and New Haven. Left at 9 a.m. on Tuesday the 29th arriving at New York at 12. noon. I went immediately to ~~25~~ 250 west 57th. st. to deliver a tripping apparatus to be used with the sheet machine recently sold to E. L. Day. Mr. Day was not there but Mr. Cameron (?) was and I showed it to him. The apperatus worked alright.

Next I went to see Mr Kampfert, who was in Newarke studying the electrical trouble there. Delivered paper to Don Fink at Electronics, and then went up to 54 st to see Mary Ellen and Welch sail away on the Monarch of Bermuda for a 10 day trip. I loaned them my movie camera for the trip.

After show at Radio City I left on the night train for Pittsburgh, arriving there at 8:30. I
Dec 30. looked up Mr. Paul Friedemann of the patent department. We saw E. J. Pollard, Henderson, and C. C. Shutt in the morning before the conference. Those present at conference:

C. H. Marcelon .03 M.I.T. Son took Chemistry
F. H. Sulliksen
C. C. Shutt
P. E. Friedeman patent

I first told them of the application that I have on file using an electrostatic system for angle-switching. Then they showed me the drawings of three applications that they now have on file. These last are by Shutt and Dawson and are along the lines of their A.I.E.E. paper of last year. In some two tubes are used, also contactors on the shaft are used.

Both methods were discussed at length bringing out that the magnetic generation method involved a special unit for each set up - Adjustment of the angle by electrical methods in place of mechanical was mentioned.

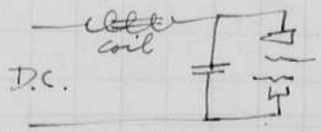
I brought up the question regarding the practical use of ignitrons or other rectifier tubes for supplying the direct current in place of exciters. Mr. Friedmann said that they had ~~an~~ a patent on this feature of 6 or 7 years duration, won by W.E. after an interference with others.

At noon the conf. was adjourned and the group had lunch together with others.

Mr. Helmund chief engineer
J. Slepian
J.A. Cox. (who has been writing to Germeshausen about ignitrons starting using strobotrons).

After lunch Slepian, Cox, and I had a conference about Ignitron starting. I discussed briefly the method and the experiments that Germeshausen and I had been doing. I recommended that it would be advisable for Germeshausen to be assigned to this job for a time in order to make recommendations. They mentioned that it might be possible to do this, obtaining an option to use the methods if they were useful to them. The cost of the investigation would be ~~boo~~ on the Westinghouse Co. At the end Mr. Rose who works with Slepian came in and we discussed the experiments that he and Kilgore did together.

After this conference on Ignitrons, we continued the one on syn. motor schemes. I brought in the use of the strobotron and showed them the circuit



(while charging condenser)

that gives the coil a very hard pull after the strobotron is fired.

I also discussed the use of the double grid strobotron, using one grid with the peaking transformer (or choke) and the other with a surge from the reluctance generator.

Dr. Friedemann took me to the research laboratory and I met Mr. Baker and Mr. Rushing who showed me their balancing machine in operation. Mr. Hanna also was there and he showed me a sound meter that they are using a great deal. I also saw the 16 mm sound projector in Hanna's lab.

Since connections to Pittsburgh are poor Mr. Ireland kindly took me down town in his car.

I took the night train to Atlantic city, Dec. 31. arriving about 10 a.m. The Haddon Hall Hotel had no room for me so I stayed at the Town House Studio at 156 S. No. Carolina Ave. next door to the Hotel. Luncheon at the Hotel with a group of Science teachers, I sat next to Prof Prather of Harvard and Prof Colney (?). and a group of students from Ga. who were attending the convention. I visited the exhibits in the afternoon but they were in the process of being torn down. Saw Mr. Masters (?) Tech graduate of '34 (?) who was working on the R.C.A. demonstration.

There were no meeting in the morning of Jan. 1. At noon I accidently ran into Mr. & Mrs. Laurence J. Webster and had lunch with them. Then we went up to the 13th floor to the meetings in the Rising room. After my movies I rode to N.Y with them and took a train to New Haven. The Garde Hotel near the station was my host that night. In the morning I saw Mr. Pugsley and Mr Robinson about the report on the vibration of a rifle barrel (model 52.) I quoted a price of $250 per gun studied - shape of barrel as a function of time after the gun was fired. Also quoted $300 for a series of shadow photos of the bullet coming from their new swift rifle. 4000 ft/sec. .22 cal

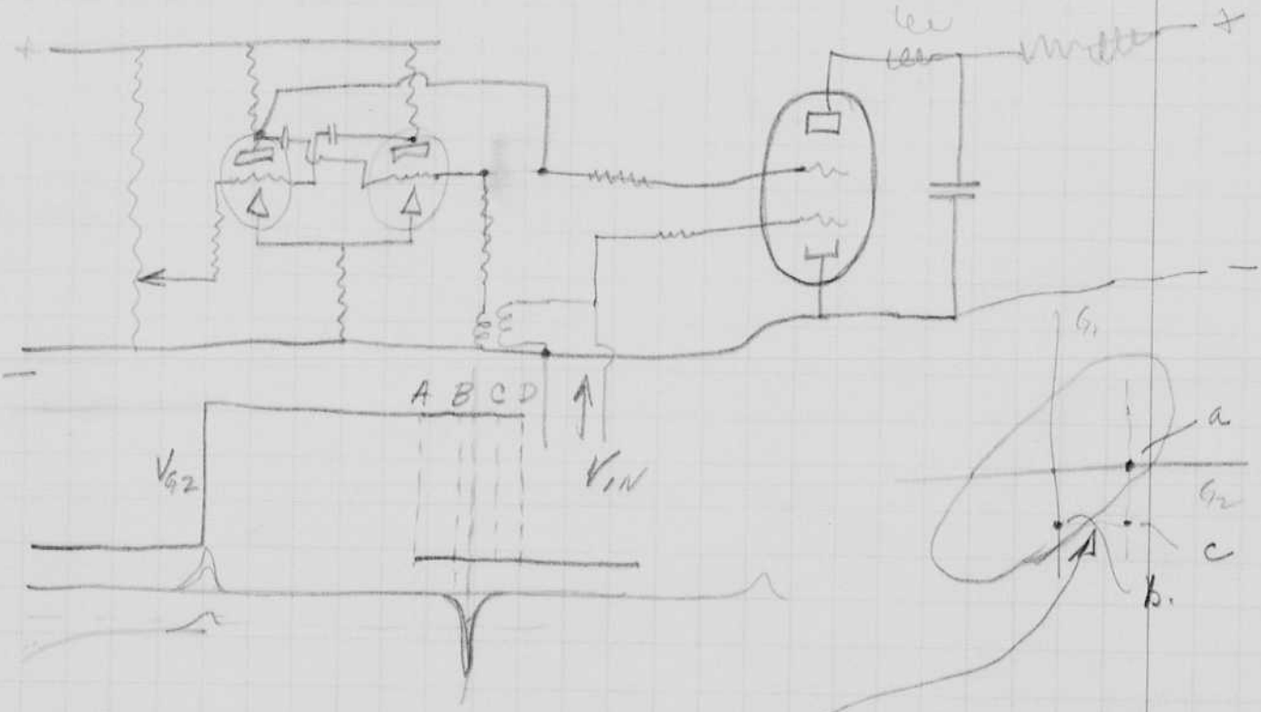
Jan 3 '37 cont.

J. E. Edgerton. Frequency relay for throwing in field switching circuit at the desired speed.

It should be possible to do this with a multivibrator type of circuit as a standard for timing. The output (peaked) from a reluctance generator would trip the multivibrator and this would condition a thyratron to fire. After a definite time the thyratron would suddenly take off the voltage. By arranging the amplitudes of the voltages correctly, control can thus be effected which compares the time between pulses for the natural period of the multivibrator osc.



a pulse at V_{in} trips the multivibrator and V_{G2} goes to a positive value (a). After a certain time it will again drops to a low value depending upon the circuit constants and characteristics of the tubes. These tubes may be pentodes where the feedback and

control grid as used ~~a~~ ~~probably~~ instead of in series as shown.

If the voltage at V_{g2} drops off at A then the tube (thyratron) will not fire (see diagram where V_{g_1} is at b on the peak). However the voltage V_{g2} has not dropped such as C and D then the leading peak voltage on grid 1 will trip the tube as at c.

The time between the peaks of the ingoing wave depend upon the speed of the machine.

For several days I have been working up a new synchronous-motor angle-switching ~~scheme~~ application. I plan to photostat the sketches and paste them in this book.

This afternoon I thought of a method of control that might have some merit. If a spark is allowed to flash between two electrodes such as spheres, there is generated very high frequency radio waves. These will be absorbed by a metalic object in a similar manner as light.

Suppose that one of the small spheres was placed on the shaft of the motor and the other in a stationary position below it so that the spark would jump when the two were at their closest point.

Mr. Paul Moore of North western Uni. School of Speech was here Feb 1 and 2. We took pictures of his vocal cords by both the stroboscopic and the high speed motion picture methods.

Sankey of S E Pittsfield telegraphed that he could not come Wednesday but wished to come after the 12 of Feb.

Feb. 7, 1937

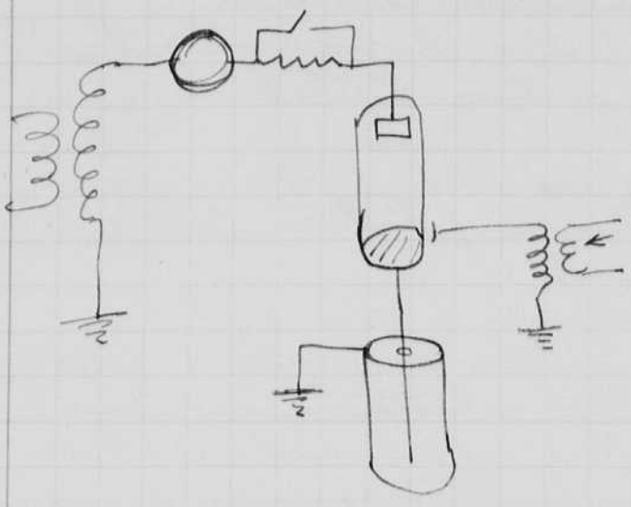
Mr. Rines was at M.I.T. on Saturday Feb 6 and saw Prof. Cady in my office. I showed him (Rines) records regarding early stroboscopic experiments in particular a demonstration on open house april 1928 in the research laboratory. M. F. Gardner who was my boss remembers the set up and the exhibit. Mr. Kershaw, mechanic remembers the device he made for the exhibit. T. S. Day could not remember the apparatus.

Mark Townsend was back on the 6th from his trip to G. E. Vapor Lamp co and Schudy G.E.Co. He said he had a fine day at Holoken at the lamp co and that he told them of his experiments with the current from Hg tubes having external bands.

Feb. 10, 1937. Second term started on Feb. 8. I have a section of 6.02, 14 students, the "C" section. Hoyer has the "A" and Timoshenko the "B". Cahoon is reading problems.

Alexander from the Simplex Wire & Cable came in this afternoon and requested data on large thyratrons for testing cables. I told him about the Hg pool tube and the strobolite started. Grier and I showed him the ignition starter circuit in operation.

– cont Cable tester for burning out the short circuits in a cable.



Strobotron or thyratron trip apparatus.

Phase control for adjusting the current.

Feb. 11, 1937 Pasadena.

Semmelhausen went out to Raytheon yesterday and got some small stems. Percy Spencer told him about a oscillograph using an ink gun and electro static deflecting plates.

Willis of the Sperry Gyroscope co. was here ~~yesterday~~ today with Draper and we discussed the photography of ball bearings. They are interested in a camera or consulting work here.

I showed the 602 class the ignitron starter that Semmelhausen wired up last week. It seemed to run fine, that is without any missed in the ignitron.

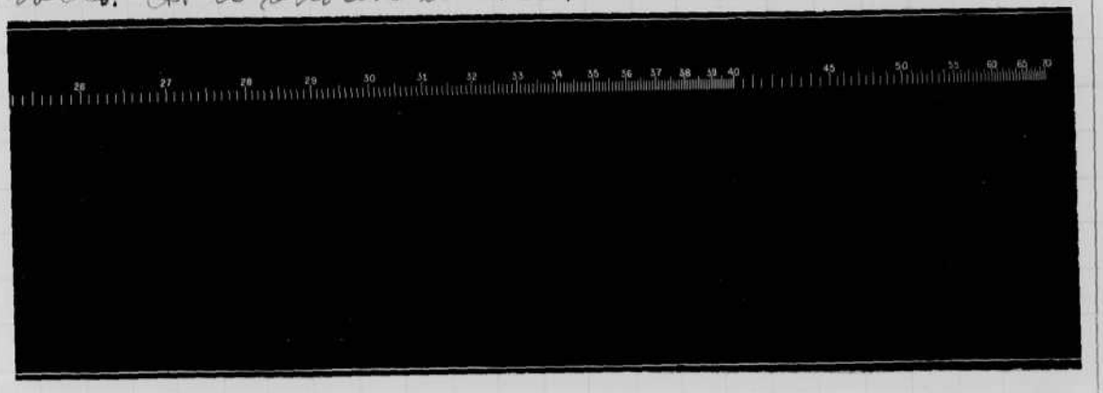
Bill Tucker has been helping me design an argon spark machine the last few days. I got an old box and some of the parts together last night. It will be something like the apparatus on page 75.

Feb 14 37. Von Tipple brought Prof Boer and his son Hans into the lab on Saturday and I showed them the last reel of movies. Bennet also was there. I took a photograph of them with the engine

lamp. f 4.5 and f 8. 24 mf 300 volts. 7 ft from camera and light to subject.

Feb. 16, 1937. H. Edgerton.

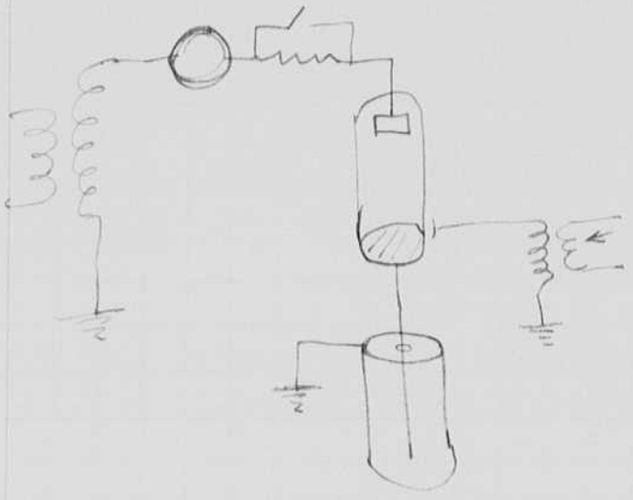
Tucker took a spectrogram of the argon lamps 12 mf (also 24) 300 volts. It is shown below.



The yellow and orange are missing. I am going to build a tube with Mg electrodes and I believe that a small amount of the material will be vaporized in light to produce some gas in time for the discharge. If the tube sputters it can be heated to drive the Mg from the walls to the end of the tube.

Merrill of the Physics dept. talked to me this a.m. about the use of the argon lamps in an enlarger. I am using a point source of light and no lens. This would work if a point source of light could be obtained.

cont Cable tester for burning out the short circuits in a cable.



Strobotron or thyratron trip apparatus.

Fine control for adjusting the current.

Dec. 11, 1937 Bridgeport.

Bennet Hansen went out to Brighton yesterday and got some small stone. He explained to him about taking a photograph using an ink gun and electrostatic deflecting plates.

Willis of the Sperry Gyroscope Co. was here ~~yesterday~~ today with Draper and we discussed the photographing of ball bearings. They are interested in a camera or something for doing work here.

I showed the 60 cycle ignition tester that Bennet Hansen wound up last week. It seems to run fine, that is without any missed in the ignition.

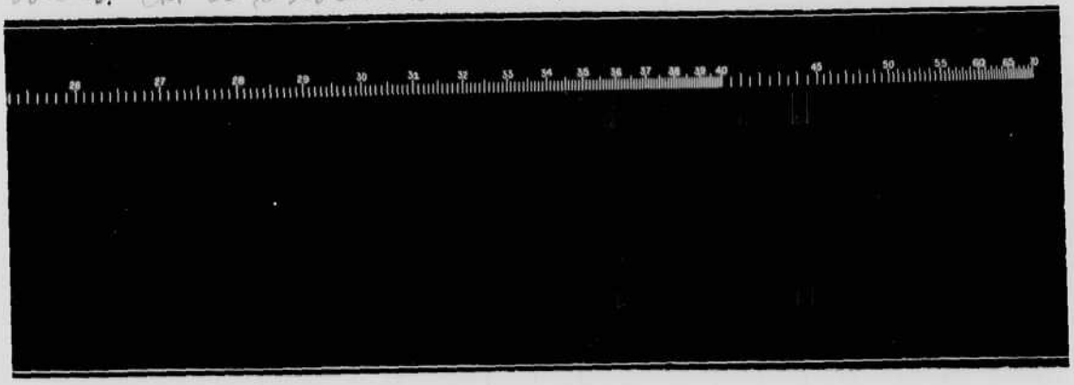
Bill Fraser has been helping me design an argon spark machine the last few days. I got an old box and some of the parts together last night. It will be something like the apparatus on page 75.

Feb 14 38. Von Tippelskirch brought Prof Boer and his son Hans into the lab on Saturday and I showed them the last reel of movies. Bennet also was there. I took a photographic of them with the argon

lamps. f 4.5 and f 8. 24 mf 300 volts. 7 ft from camera and light to subject.

Feb. 16, 1937. Hodgson.

Tucher took a spectrogram of the argon lamps 12 mf 2 to 20) 300 volts. It is shown below.



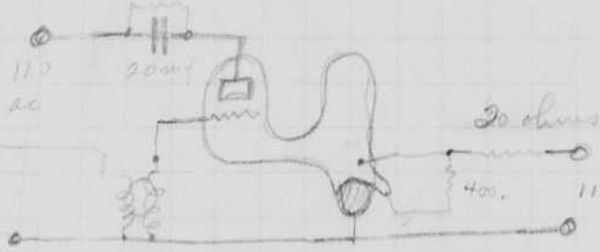
The yellow and orange are missing. I am going to build a tube with Mg electrodes and I think that a small amount of this material will be vaporized in light to produce some gas in time for the discharge. If this tube sputters it can be heated to drive the Mg. from the walls to the end of the tube.

Merrill of the Physics dept. talked to me this a.m. about the use of the argon lamps in an emergency. I suggested using a point source of light and no lens. This would work if a point source of light could be obtained.

July 23 1927
Mr. Edgerton

Yesterday Dick Cutts and Kenneth Beardsley were here and discussed early stroboscope experiments with Mr. Rines. Their testimony may be used in a patent interference with R. Troulsen regarding a fundamental patent claim.

I plan to hook up the earliest model if I can find the tubes etc.



$RC = .01$

$R = \frac{.01 \cdot 10^6}{20} = \frac{10^3}{2} = 500$ ohms.

The above experiment was started today. Cutts and Rines want to look at it on Friday morning

Mr. Ryder who works in Fitzpatrick's office told me over the phone today that the tube #448141 was made on March 17 1927 and is rated 20 amps 200 volts.

Brown gave me the bulletin on the new Magnetic Stroboscope that came from the General Electric in Jan. 1928.

I sent this with Cutts and Beardsleys thesis to Mr. Rines. Also tube # 448141 which had no mercury in it.

I saw Barrow in the hall today and told him that I was planning to see him within a week or so about the short wave radio method of synchronizing a synchronous motor at the least angle.

this method was explained to him in Walton's on Jan 13 or 14 while eating.

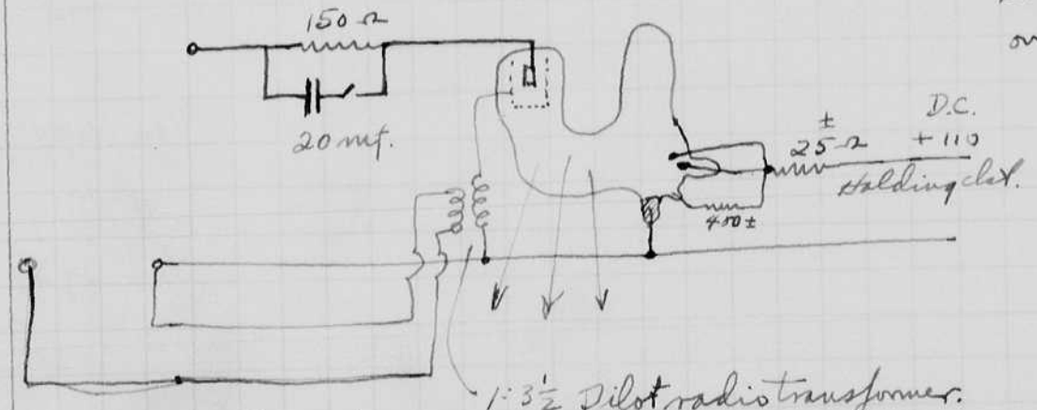
Mr. Alger phoned from Schenectady on Friday Feb. 19 about 9 30 am about the synchronous motor synchronizing schemes. I told him about the trip to Westinghouse during the vacations.

Esther and I left about 11 am. for Proctor (Friday 19th). Vt. to talk to the University club there. We were the guests of Mr. & Mrs. Redfield Proctor. On the 20th we went to Middlebury and saw the Nottingham's and White, also his parents. The Ski jumping at the college affair was quite exciting. Returned to Belmont that afternoon.

Feb. 24, 1931.

I wired up the circuit on p 120 which was started yesterday

this circuit was shown in operation to Mr. Rines and to Mr Cutts on or about Feb 26 31



Works ok

~~Schol~~ Shoults called on the phone this aft. from Schenectady (G.E.) and mentioned coming over to see about sync. motor schemes this weekend. He may come sunday.

Apr 15 37 cont.

Mr. Cooley came from Los Angeles on Wednesday and since then he and Tucker and Zemansky have been working on the microscope setup for photographing oil samples to show electrical demulsification.

Griffin from Harvard was here on Monday night April 12 with 6 bats and a photo cell setup by Tucker aided & assisted by Cooley getting the light at the correct time.

April 25. 1937. Mr. Cooley and Mr. Roberts (who came on the 16th of April) worked with us the 16 17 18 and 19 taking high-speed motion pictures of electrical and chemical treatment of emulsified oils. They seemed satisfied with the results and took all the films when they left on the 20th.

I took the double argon lamp flash out fit to New York with me on the night of April 22. Welch helped to carry it to the train. I was met in New York by Gino Milé at 8:30 in the Penn station and took a cab to the Dexter Studio on 47th St between 5 and 6th avenue. Mr. Arthur Murray was at this studio and we set up the flash out fit in the main part. Bill Jackson did the developing. Two models performed. One shot a bow and arrow as she jumped into the air. The other jumped into the air and the picture was taken at that instant.

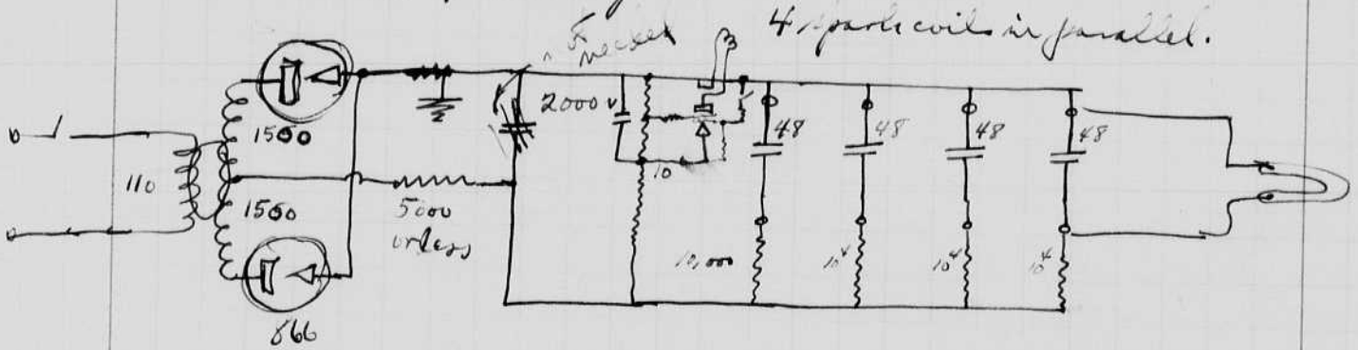
One lamp had 36 mf at 3000 volts on it and was placed quite high at the side with the reflector at a 45° angle, seven ft from the subject. The other lamp was 12 ft from the subject and was located at the camera. A 12 mf condenser was across it.

The first picture was taken at f 6.3 on orthochromatic film and the exposure was ok with 12 minute development. Other shots were taken on 35 mm film with the same setting and the exposure was about the same.

The circuit of the flash unit is on page 75 with minor exceptions, for instance there is only one slot for firing both spark coils.

More light is needed so that photographs at f 8, 11, & 16 of large subjects can be taken. Reflectors with more efficiency will help greatly. I would like to see about 10 times as much light, and it can be obtained by means of more condensers and lights.

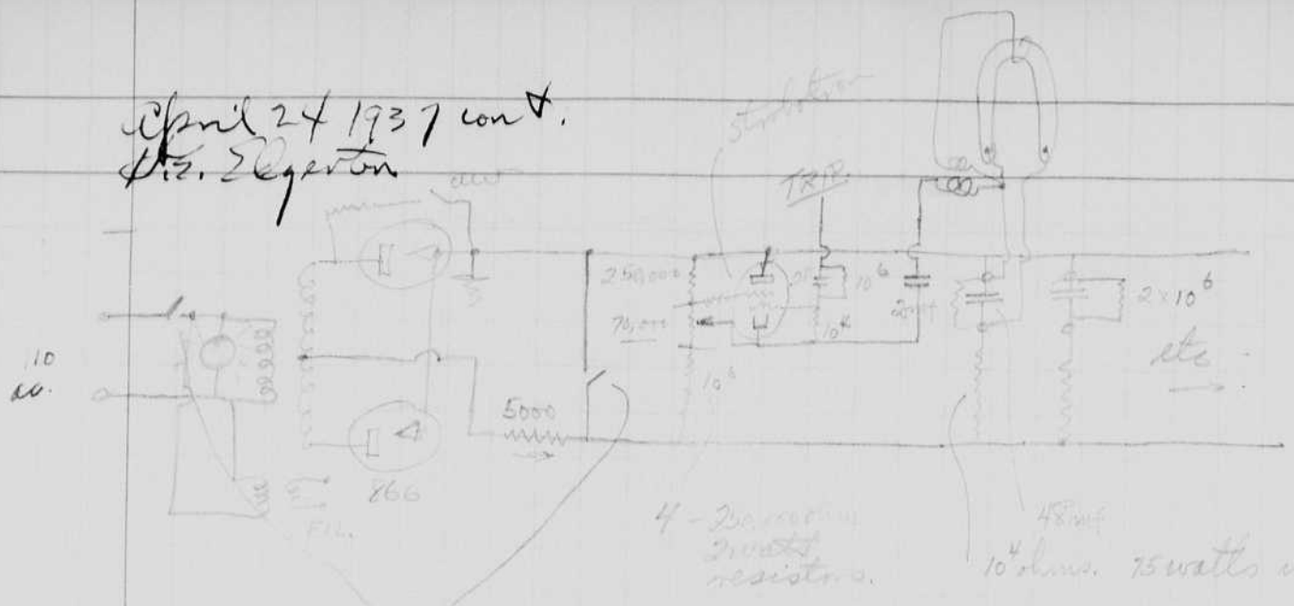
I am going to ~~try~~ design a new unit with 48 mf at 2000 volts on each lamp. and with 4 lamps.



The spark coils should be put in series with condensers as in the unit I used, so that the spark will be the same no matter how many lamps are used. A 2 meg ohm leak should be put across each of the 48 mf condensers. $RC = 48 \times 10^{-6} \times 2 \times 10^{6} = 96$ seconds.

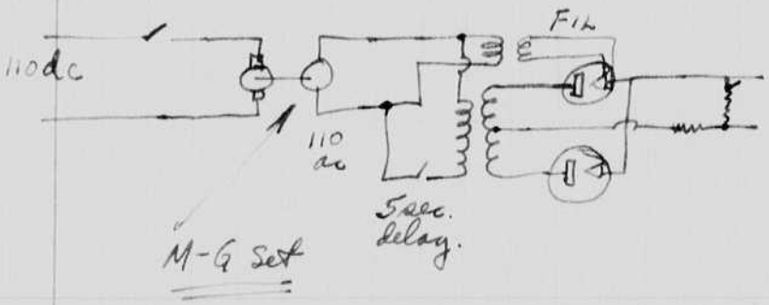
On the evening of Apr 23 I gave a talk at the Physics Club in Philadelphia at the Univ of Pa. I stayed that night with Mr. Henry B. Allen. Dinner at the Rittenhouse Club with Dr. Barnes and Mr. Allen. John Bancroft about to be engaged to Allen's daughter

April 24 1937 con't.
Mr. Edgerton



the two switches are to be ganged together so that the shorting switch closes when the power switch is off.

If used in a d-c district a motor-generator set will be needed.



The short circuiting switch should be a relay arranged to drop shut when the plate transformer is off. It would be connected across the primary of the plate transformer.

April 29 1937.

Last night I pumped some tubes for the 545 stroboscope. they were sealed off with about 1 or 1½ cm of neon (1) and argon (3) and a mixture (1).

Also made two lamps for flash machine. One with 2 cm of neon & 8 of argon, the other with 4 cm of .. and 8 of argon. The neon brings in some red and yellow which balances the color of the flash.

A & M Roberts

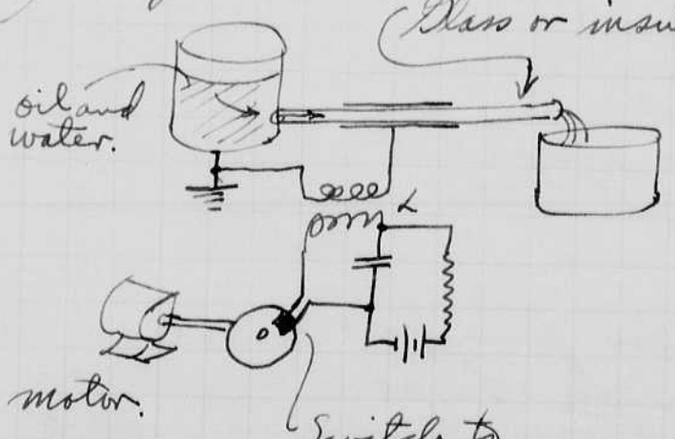
I spent the last few days rebuilding the old spark machine which was in the oscillograph case. Before we had 4 - 12 mf 660 volt oil condensers in series on an open spark. 16000 volts. Now these are in parallel 48 mf and they charge to about 3800 volts. 1.38×10^6 ohms $\times$ 2.8 ma = 3860 volts. A strobolite is used as a trip as in the diagram on p 146. The new circuits works fine. I used a tube having 4 cm of neon and about 8 cm (+?) of argon which gives a good color. This lamp with neon and argon does not "check" on the inner surface of the glass as do the lamps with argon.

Oil treatment to remove water

The below method should be especially good for treating oil with large amounts of water which is highly conducting. The emulsion of water and oil are driven through glass tubes about which are external electrodes. A high voltage is impressed on the external electrodes for a very short interval of time in order to treat the oil and break down the emulsion. Circuits similar to those that we use for our stroboscopic lamps should be well adapted for this purpose.



The breaker circuit can also be similar to auto ignition circuits that break a current.

Half-Cycle Spot-Welder Control

T. S. Gray and W. B. Nottingham[1]
Massachusetts Institute of Technology, Cambridge, Massachusetts
(Received December 23, 1936)

A circuit for controlling a small spot-welder is described which utilizes simple, inexpensive, cold cathode tubes. Variation of the welding heat is accomplished by control of the fraction of a single half-cycle during which current is supplied to the welder transformer. Increased pressure is found to be necessary for satisfactory welding.

Introduction

IT is generally recognized by the research worker who uses a spot-welder in the construction of special apparatus that a high current applied[2] for a precisely determined and very short period of time is desired for welding operations.[3] Commercial equipment no doubt meets the demands of many of the users of large spot-welders; however, it has long been felt that a simple circuit which could be adapted to standard low power welders (1 to 3 kva) would be of value. Circuits of this type have been experimented with by one of us (WBN) for the past three years with the final result that the one described here is considered by us to be both the simplest, cheapest, and, at the same time, the most reliable of all those tried. It has been used extensively at this institute in both the physics and electrical engineering departments.

Strobotron and Band-Igniter Arc Tubes

In this circuit, which is shown in Fig. 1, the two elements of prime importance incorporated are the "strobotron" (T_2) and the "band-igniter arc tube" (T_1). The band-igniter arc tube is shown schematically in Fig. 2, and consists of the simplest pool-type mercury arc. We have given our tubes a careful exhaust, using vacuum-distilled mercury distilled over to the tube after it has been thoroughly baked. The anode was heated by induction, and the tube finally operated for some hours while on the pumps before it was sealed off. The development of this tube dates back at least to Peter Cooper Hewitt,[4] but has

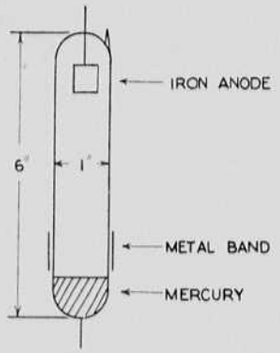

FIG. 2. Band-igniter mercury arc tube.

recently been used extensively by H. E. Edgerton[5] and his collaborators.

Since the strobotron has been developed quite recently,[6] and although it is closely related to the "grid-glow tube" and the "thyratron," a short explanation of its operation is perhaps justified. Fig. 3 shows the four essential elements, which are (1) cathode, (2) an inner grid, (3) an outer grid, and (4) an anode. All leads are connected to the four prongs of a standard radio tube base.[7] The type of discharge observed in the tube may be either a glow or an arc, depending on the current conducted.

Typical characteristics as tabulated elsewhere[8] are in Table I.

More detailed information as to the operation of one of these tubes may be had from a typical diagram of the starting characteristics[8] shown in Fig. 4. In many cases, the anode-cathode voltage is constant and set by the circuit. Either of the grids, or both, may be varied in their potential with respect to the cathode to start the discharge. Such conduction is initiated when the difference of potential between any two elements exceeds values characteristic of the tube as tabulated in Table I. The potential of the grids with respect to the cathode can be located on a two-dimensional diagram, as shown in Fig. 4. The loop of this diagram encloses the region of nonoperation for an anode potential of 320 volts.

To illustrate this, let it be assumed that the

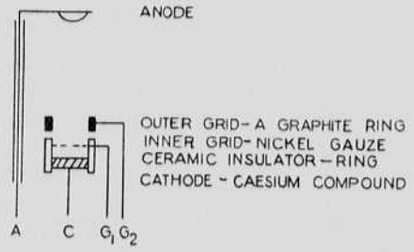

FIG. 3. Arrangement of elements in the strobotron.

potential of the outer grid is set at any arbitrary value, such as +70 volts measured from the cathode. The vertical dotted line through the point +70 on the horizontal axis cuts the loop shown at −25 volts and at +125 volts. This means that as long as the inner grid voltage is between these limits when the anode potential of 320 volts is applied, the strobotron will remain nonconducting. Conductivity sets in, however, in case the inner grid is made more negative than −25 volts, or more positive than +125 volts. Thus, if any arbitrary values be assigned to the inner and outer grid potentials and the corresponding point be located on the plot shown in Fig. 4, it will be seen at once whether or not the tube will conduct depending on where the point falls. If the point falls inside the loop, then the strobotron *does not conduct*. If the point falls outside the loop, then the tube *does conduct*.

OPERATION OF WELDER CIRCUIT

The circuit shown in Fig. 1 is designed to operate from a mid-tapped 230-volt 60-c.p.s. line. The heavy lines of the figure show the connection to the welder-transformer primary in which the mercury tube, designated by T_1, serves as a simple switch. The strobotron circuit serves to deliver to the starting band on T_1 a high voltage pulse accurately timed with respect to the 230-volt 60-c.p.s. wave normally impressed across T_1, thus causing it to become conducting for that fraction of the positive half-cycle which remains after the starting-band pulse is delivered. Fig. 5 shows the voltage wave-forms in the circuit as observed with a cathode-ray oscilloscope. The arc extinguishes itself at the end of the half-cycle and the tube remains nonconducting until another pulse is delivered to the starting band.

The type 80 rectifier tube T_3 serves to charge up the 4 mf condenser C_2 which, when discharged through the strobotron and the primary of the Ford spark coil Tr_2, generates the high voltage pulse used by the starting band to set up the arc in the mercury tube T_1.

Between welding operations, the outer grid of the strobotron is maintained at cathode potential (i.e., zero) while the inner grid has impressed upon it a 60-cycle "peaked" wave of a maximum amplitude of about 50 to 60 volts obtained from a potential divider $R_7 - R_8$ across a peaking transformer[9] Tr_3 whose primary is supplied from a "resistance-condenser" phase shift circuit R_{10} and C_4. The negative peak of this wave, with respect to the positive peak of the line voltage, can be varied at will from 20° to 160° lagging. Referring to Fig. 4, we see that as long as the outer grid potential is zero, the point representing the inner grid potential remains inside the loop for all parts of the cycle. Line *ab* represents the locus of this point. When the welding pulse is desired, the switch S is closed. At the corresponding time "t_1," which may be anywhere in the cycle, the voltage of the outer grid rises to about 70 volts, as shown in Fig. 5, as the 0.5 mf condenser C_1 is charged to that value by the potential divider R_4. The condenser discharges through the resistor R_2 in an exponential manner, but since the time constant is greater than 0.05 second, the voltage of the outer grid remains substantially constant as in Fig. 5 (*a*). With a shift of outer grid potential from 0 to +70 volts, the locus of the peaked wave *ab* in Fig. 4 shifts to the right and crosses into the "conducting" region at point "*c*." The pulse then delivered to the starting band ignites the mercury arc at the time "t_2" in Fig. 5, and conduction through the mercury-arc tube and welder transformer continues for the remainder of the half-cycle.[10] Since the cross over into the conducting region of Fig. 4 occurs at a well-defined point on the peaked wave, and, since the angle of lag, θ, between the negative peaked wave and the line voltage can be controlled by the "resistance-condenser" phase shifter consisting of R_{10} and C_4, it is clear that the starting pulse can be delivered to the band on T_1 at an accurately preassigned time measured with respect to the a.c. voltage applied to the tube T_1 and thus the fraction of the cycle during which it conducts can be controlled.

There are two methods of controlling the intensity of the welding heat using this circuit, one being by phase control, and the other through amplitude control by means of R_1 in the primary line. The condenser C_1 is discharged by the grid current when the strobotron becomes conducting, and as long as the switch S remains closed, it can charge up to only one-third its normal voltage because of the current drain through R_2. The

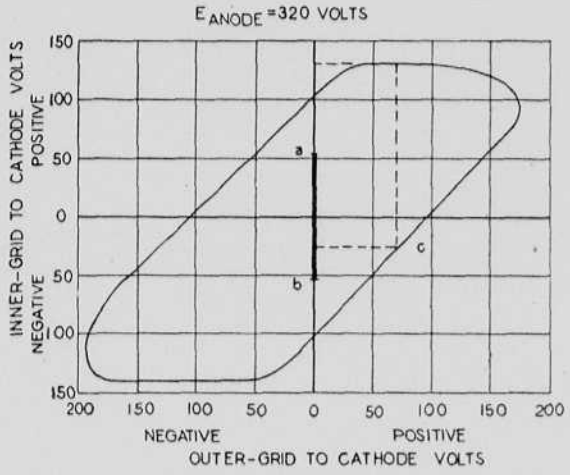

FIG. 4. Relation of grid voltages for starting the strobotron tube.

TABLE I. *Strobotron data.* Number of electrodes, 4: caesium covered cold cathode: gas, 1.5 cm, neon. Typical initial glow potentials in volts.

POSITIVE ELECTRODE	NEGATIVE ELECTRODE	NORMAL POTENTIAL DIFFERENCE	EXPECTED VARIATIONS

Cathode	Outer grid	200	+40–60
Anode	Inner grid	600	+50–40
Average anode current (max.)			100 milliamperes
Instantaneous anode current (max.)			250 amperes
Average tube drop for arc			20 volts
Average tube drop for glow			80 volts

[9] The transformer we have used is designed to operate from 115 volts a.c. with a 5000 ohm resistor in series with the primary, and to deliver a peaked voltage of about 110 volts. If a different transformer is used, resistors R_7, R_8, and R_9 should be modified.

[10] Actually, conduction continues for a short time into the next negative half-cycle, due to the leakage inductance of the transformer.

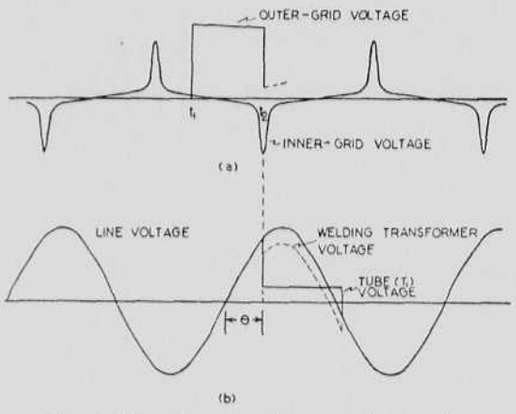

FIG. 5. Wave form of voltages in the circuit.

contact point on R_4 is adjusted so that the corresponding shift in outer grid voltage is insufficient to cause the locus of the peaked wave in Fig. 4 to cross into the conducting region, and therefore only one pulse is obtained each time the switch is closed. The anode voltage of the mercury arc tube T_1 must be more positive than a critical value of about 50 volts in order that an arc start when the external band is excited. The useful range of phase control is therefore from about 10° to 170°.

PRESSURE REQUIREMENTS FOR STRONG WELDS

A spot weld produced by a very high current over a short time has the advantage that the neighboring metal does not become hot. To force the high current through the transformer, it has been found suitable to operate the primary winding normally rated at 115 volts from the 230 volt line. Peak currents of 300 amperes occur in the primary line, thus it is necessary to use heavy wiring for low resistance.

With the intense local heating at the weld, higher than normal pressure is required to prevent vaporization of the material and to provide the requisite forging action. By means of a pendulum type tensile tester, we have measured the strength of about two hundred welds made between round nickel wires of the three sizes, 10, 35, and 50 mils in diameter, using various values of current and force. The results of these tests indicate that a force of 40 lb. is desirable to produce the best welds in the larger sizes of wire, but that for the smallest wire a force of 20 lb., together with a reduced current, is satisfactory.
